ILF

ILCHESTER, or Ilchester, the Isca di of Potain, is a borough and market town of England, in Somersetshire. It is situated on the river Yeo, over which there is a stone bridge of two large arches, and consists of four streets, which are but indifferently built. The only remaining church out of six is dedicated to St. Mary; and has an octagonal tower 50 feet high, constructed of Roman stone. There are also places of worship for the dissenters. The assizes were formerly held here under a patent granted by Edward III., but they are now only held here in rotation with Wells, Taunton, and Bridgewater. The county court-house is a good building, and so is the new county gaol, which is built on Mr. Howard's plan. Opposite to it, on the other side of the river, stand the remains of the ancient hospital of Whitehall, founded about 1221, by William Dennis or Desus, for the entertainment of pilgrims or poor travellers. There is also to be seen here the remains of a house of Black Friars, which had a subterraneous passage leading to the White-hall munsters.

When this part of the country was in the possession of the Romans, Ilchester was one of their principal stations, and was fortified with a strong wall and deep ditch, which they filled with water from the Yeo. Vestiges of these ancient works are still visible. There are held at Ilchester three fairs annually. The manufacture of thread lace, which was once considerable, has now declined; but it has been succeeded by a small silk manufacture. This town is famous as being the birth-place of the celebrated Roger Bacon. The following is the population of the borough and parish for 1811.

Number of inhabited houses .................................. 85
Number of families ........................................... 140
Do. employed in trade .......................................... 42
Population ..................................................... 610

ILFRACOMBE is a sea-port and market-town of

ILF

Ilfracombe, England, in the county of Devon. It is situated on the sides and at the base of steep ground on the borders of the Bristol Channel. The town contains a number of good houses for the accommodation of bathers, which extend along the side of the harbour, and for nearly a mile to the west of it, where there is a good pebbly shore, and convenient bathing machines. The church stands in the upper part of the town. It is a large plain structure, and contains a handsome monument, erected, at the national expense, to the memory of Captain Bowen.

The harbour of Ilfracombe resembles a natural basin, surrounded by craggy heights, covered with foliage. The rocks ascend in a semicircular sweep on three sides, and on the north side a mass of rock projects nearly half way across the mouth of the recess, and protects the little cove from the northern tempests. This rock rises almost to a point, where a light house, resembling a church, is erected. "Along the side of the same rock," says Mr. Warner, in his Walk through the Western Counties, "to the opening of the harbour, runs an artificial pier, judiciously constructed, to prevent the accumulation of the sand; so that by the joint assistance of the natural barrier, and this piece of masonry, ships of 300 tons burthen may ride completely land-locked, and of course perfectly safe from all the violence of the weather. Before the year 1751, this pier was 880 feet long; but having been destroyed by the wind, an act of parliament was passed for repairing and enlarging it and the harbour. It was partly rebuilt, lengthened, and enlarged, in 1760, by Sir Bourchier Wrey, Bart.

There is a daily intercourse, by means of a packet, which sails every other tide, with the town of Swansea, on the opposite coast of Wales.

On a high point near the bay, is a summer house, erected by Sir Bourchier Wrey, which commands a fine prospect. Watermouth, the seat of Joseph Davie, Esq., is beautifully situated on an eminence about three miles to the east of the town.
The vessels which belong to Lifescombe are chiefly employed in the coasting trade, in conveying ore, corn, &c. from Cornwall and Devonshire to Bristol, and also in fishing.

The following was the population of the town and parish in 1811.

ILLAC PASSION. See Mediciné.

ILLÉ AND VILLAINÉ, is the name of one of the north-west departments of France, which derives its name from the Ille and Villaine, two rivers which unite at Rennes, the capital of the department. The soil of this department is in general ill-fitted for culture, nevertheless below Rennes and St. Malo, corn, hemp, and fruits, are produced in abundance. At a short distance from Rennes, is the farm of Prevalais, where the butter is made that is so famous in every part of France. The inland commerce of this department consists principally of its natural productions, which are corn, lint, hemp, wood, cattle, butter, mines of lead, oysters, and fish.

The department contains 7182 square kilometers, or 364 square leagues. The forests, of which three-fourths belong to the nation, occupy 54,000 or 55,000 acres. The contributions in the year 1802 were 421,093 francs; and the number of inhabitants is 488,605. The principal towns are, Population.

ILLÉGITIMACY. See Law.

ILLINOIS TERRITORY is one of the northern of the United States of North America. It derives its name from the river Illinois, an Indian word, which signifies a man of full age, or in the vigour of his years.

This territory lies between 37° and 49° 37' of North Lat. and between Long. 85° 45' and 95° 6' West. It is about 870 miles long from the Ohio to the northern line, and has the following breadths, 650 miles, 200, 150, and 50. It contains 200,000 square miles, exclusive of part of the waters of the lakes Superior and Michigan.

It is bounded by Upper Canada on the north, by the Indian territory on the east, by the river Illinois on the south-east, and by Louisiana on the west, from which it is separated by the Mississippi.

The part of this territory which is settled by the white people, is divided into two counties, St Clair and Randolph; the first of which contains nine towns and 5007 inhabitants, and the second three towns and 7275 inhabitants. In 1800, the whole population was 215, and in 1810 it amounted to 12,282.

The principal towns of the Illinois territory are Kaskasia, the capital, which is situated on the river of the same name, and contains 100 well built houses, and 622 inhabitants; Cahokia, situated on the southern side of Cahokia Creek, and containing 711 inhabitants; and Goshen, the capital of St Clair county, which has 1725 inhabitants.

The chief rivers are the Mississippi, the Illinois, the Wabash, the Ouiscnsin, the Fox river, the Chippeway, the St Croix, the St Louis, the Winnipeg, the Dove, the Seseme Quian, the Kasaskia, the Auusave, and the Little Wabash.

The principal lakes are Lakes Michigan, Superior, Rainy Lake, Red Lake, about 60 miles in circumference, and nearly round; Lake Pepin, about 20 miles long and 6 broad; Lake Winnebago, 15 miles long and 6 wide; and lake Illinois, about 20 miles long and 3 wide.

The country between the rivers Kasaskia and Illinois, which is a distance of about 84 miles, is a rich and level tract of land, terminating in a high ridge. The last of these rivers is bordered by fine meadows, and the soil of the country is in general of a very superior quality.

Fort Massac, which was built by the French on the west bank of the Ohio, is a port of entry; and in the 4th quarter of 1803, foreign articles were exported to the value of 17,320 dollars.

The principal mines of this territory are those of Natural copper and lead. On Mine river, a western branch of history, the Illinois, there is a rich copper mine. On the south shore of Lake Superior, there are many mines of pure copper. About 9 miles from the mouth of Iron river there is another copper mine; and the same metal is also found in great quantities on Middle Island, nineteen leagues north-west of Iron river. The purest lead ore is found in immense quantities on the banks of the Ouiscnsin.

The banks of the rivers abound with buffaloes, deer, elk, turkeys, ducks, teal, geese, swans, cranes, pelicans, pheasants, partridges. The sturgeon and the picanou, and plenty of fish, are found in the lakes and rivers.

The vegetables of this district are the oak, hickory, chestnut, mulberry, hops, dyeing drugs, medicinal plants of various kinds, and excellent wild grapes, from which, in the year 1797, the French settlers made 110 bogsheads of strong wine.

Before the year 1766 the French had settlements at History, Kaskasia, Cahokia, &c. but they were at that time driven out by the British, who held the country till the revolution. In the year 1780, there were 12 Indian tribes in this territory, which were estimated to contain 8500 fighting men. See Morse’s System of Geography, Boston, 1814.

ILLUMINATI, a secret association which existed in Germany, some time previous to the French revolution, and which has been supposed to have been connected with the masonic institutions on the continent. This association was founded in 1775, by Dr. Adam Weishaupt, professor of canon law in the university of Ingolstadt. The professed objects of the institution were to introduce more enlightened ideas of government, to disseminate a knowledge of the sciences, and to promote the interests of virtue; but its members have been accused, not without some appearance of reason, of inculcating speculative opinions, equally hostile to the principles of sound religion and social order.

Soon after the commencement of the French revolution, the attention of the public was eagerly directed towards the plan and objects of this association, which
then indeed no longer existed, but whose members were supposed to have exercised no considerable portion of activity and influence, in producing the peculiar temper, and directing the political events of the times; and the works of the Abbé Barruel and Professor Robison, in which the secret views and active exertions of the order were sought to be developed, were perused with extraordinary interest and avidity. It seems now, however, to be pretty generally acknowledged, that these, and other authors, were induced to ascribe to this institution an extent and an influence, which in reality it never possessed; and that, in particular, the secret machinations and wicked practices of the illuminati were excessively magnified by the heated imagination of the French priest, and the honest credulity of our distinguished countrymen. The history of the order of the illuminati indeed is involved in much obscurity; and this circumstance, which has led some, perhaps naturally enough, to overrate its influence, (omnia ignota pro magnifico) affords to our mind no mean evidence of its insignificance. Time, however, has contributed to diminish the imaginary importance of this formidable association; and the following short statement contains the general result of all the information we have been able to obtain, relative to this once interesting, but now almost forgotten subject.

It is well known, that since the period of the reformation, the various states and principalities of the German empire were not more strictly defined by territorial limits, than by different professions of faith. Throughout those provinces which had adopted the new doctrines, a spirit of liberal inquiry was excited, which, if unobstructed by other causes, promised to prove highly beneficial to science, and to the interests of humanity; while, at the same time, the diffusion of useful knowledge and enlightened opinions was generally encouraged, in a greater or less degree, by the different governments. A sort of rivalry, indeed, took place among the several principalities, and each, according to its means, endeavoured to surpass its neighbours in the number and the splendour of its literary institutions. In those states, on the other hand, which adhered to the doctrines and discipline of the Roman church, an opposite line of policy was pursued by the rulers. Afraid, it would seem, lest the light of science should dispel the most prejudiced, and upon which they conceived that the security of their civil and religious establishments principally depended, they endeavoured to isolate themselves from their more enlightened neighbours, to exercise a species of surveillance over the intellects of their subjects, by means of edicts levied against the commerce of literature, and to oppose the ameliorate of ignorance to the contagion of knowledge. But it was no easy matter to exclude this dreaded pestilence, or to keep the sick separate from the uninfectcd, in a country whose inhabitants boasted one common origin, and spoke one common language, and possessed the means of frequent intercourse with each other. Some scattered rays of the surrounding light would easily penetrate the intervening gloom,—enough at least to show those upon whom they felt the darkness in which they were placed, and to excite in them a desire for a more extensive prospect. In none of the provinces of Germany was this interdiction of literature more strictly and oppressively exercised than in Bavaria, under the most bigotted administration of the elector Charles Theodore; and accordingly, it is precisely in this province that we find the natural result of such absurd and barbarous policy. Men of enlightened minds could not fail to look with abhorrence upon regulations, which were calculated to check the natural progress of knowledge, and would readily endeavour to convert the means of evading the existing laws. These means, however, could only be concerted in secret; and to this simple origin, we believe, the institution founded by Weishaupt may truly be ascribed, however widely the conduct of its members may have afterwards deviated from the original object. There is undoubtedly something dangerous in the very nature and constitution of such a secret association, however pure the intentions of its founders may have been. Secrecy implies something illegal in the object; and such a society being under no regular control, its views may easily become enlarged, and its influence perverted to improper purposes. Some zealous enthusiasts among the illuminati, may have contemplated the possibility of directing the existing governments, by means of the powerful but pacific influence of a secret association; others, imbued with the absurd theory of the infinite perfectibility of the human mind, may have considered such an institution as calculated to promote their romantic and unattainable views; while a third class, perhaps, consisting of more cunning than enthusiastic, full of ambition, but destitute of principle, may have looked upon a society so constituted, as best adapted to the conception of their wicked designs. Yet the society of the illuminati never seems to have acquired any extensive influence; nor does it appear to have possessed any ramifications beyond the limits of Germany. Throughout the whole of that large empire it produced no extraordinary or permanent effects; and a few years after the suppression of the order in 1787, it was nearly forgotten in the very country where it had boasted an ephemeral existence. It was chiefly on account of its supposed influence in producing the catastrophe of the French Revolution, that the ashes of this short-lived association were raised up from the chancel-house of oblivion, and a degree of posthumous celebrity conferred upon its proceedings. The suppression, however, is entirely unsupported by evidence, and has been sufficiently refuted by M. Mounier and others.

But whatever may have been the extent, influence, and real objects of this society, there can be no doubt that its constitution was illegal, and the opinions and practices of its members highly dangerous to civil and religious government. The suppression of the order, therefore, was justifiable upon every principle of right and expediency. A great mass of publications has appeared upon the subject of this article; but the substance of the whole will be found in the works of the Abbé Barruel, Professor Robison, and M. Mounier. (2)
centre of the town is a new built market-house and
shambles. An excellent free school was founded here
in 1530, by Humphry Waldron and Henry Greenfield,
and well endowed. The cloth manufacture once flour-
ished here in a very great degree, but, though still
considerable, it has greatly decreased. Ilminster is
surrounded with fine orchards, and very extensive pros-
spects are commanded by the neighbouring eminences.

The following is the abstract of the population for
the town and parish for 1811:

**Image.** See Optics.

**Imaginary Expressions or Quantities,** or im-
possible quantities in Algebra, are such as have the sym-
bol $\sqrt{-1}$ in their analytic expression. They are so
called, because the square root of a negative quantity
has no real existence; for whether a quantity be
positive or negative, its square is a positive quantity.

The origin and nature of imaginary quantities have
been explained in our article Algebra, § 189—193.
They are there shown to be of two distinct kinds, one
which is altogether impossible, and can denote no real
quantity; and another, which denotes real quantities.

The first class, when reduced to their most simple
expression, have this form $a + \sqrt{-b^2}$, or $a + b\sqrt{-1}$,
where $a$ may in some cases be $= 0$. These occur,
when a problem is to be resolved which from its nature
requires that the data be contained within certain lim-
its in respect of magnitude, while at the same time,
in the particular case proposed, they pass those limits.

For example, if it be required to construct a right
angled triangle, the hypothesis on which shall be
equal to a given line $a$, and one of the sides equal to
another given line $b$; from the nature of the case, $a$
must be greater than $b$; and if, in the particular state
of the data, $a$ be less than $b$, the thing required cannot
be done.

The unknown side of the triangle expressed in sym-
ols, algebraically is $\sqrt{a^2 - b^2}$; now, if $b$ be greater
than $a$, the quantity $a^2 - b^2$ is negative, and the ex-
pression for the side of the triangle has the form
$\sqrt{-a^2} = \sqrt{-1}$, which is imaginary. The impos-
sibility of giving a significant numerical value to this
symbol, corresponds, in this instance, to the impossibil-
ity of placing between a given point, and a straight
line given by position, a line of a given length, that is
shorter than the perpendicular from the point on the
line, or, which is the same, of determining the intersec-
tion of a straight line, and a circle which lies wholly on
one side of the line.

In **Geometrical Problems,** passing the first order,
the unknown quantities are determined either by the
intersection of a straight line with a curve, or else by
the intersection of two curves: Now, although it may
be possible that the conditions to be fulfilled in a
problem may be all satisfied at once, yet in many cases
there will be limitations of the data; for example, by
one condition a straight line may be required to be of
a given length; and by another, that its extremities
be on the circumference of a given circle. These can
only be satisfied at once, when the straight line is less
than the diameter. In like manner, one condition re-
quiring that a straight line touch a circle, and another,
that it pass through a certain point, can both be satis-
filed only when the point is without the circle. When
the **data** of a problem are in this way limited, as often
as they cannot be all satisfied at once, the incongruity
is indicated geometrically by their being no intersec-
tion of the lines, which should meet and determine the
unknown quantities; and algebraically, by the impos-
sible symbol $\sqrt{-1}$ entering into their values, and in
such a way as not to admit of its being eliminated.

The presence of the symbol $\sqrt{-1}$, in the algebraic
expression for a quantity, serves not only to shew the
impossibility of finding that quantity in the particular
state of the data, but it also indicates the boundary
which separates the possible from the impossible cases,
and thus determines the greatest and least values that
is can be given to the different quantities concerned in
the problem.

For example, let it be required to find a fraction
which, together with its reciprocal, shall be equal to a
given number, and also the limits within which the
problem is possible.

Calling the fraction $x$, and the given number $2a$,
the condition to be satisfied will be expressed by this
equation:

$$x + \frac{1}{x} = 2a,$$

which produces the quadratic equation $x^2 - 2ax + 1 = 0$,
and, this resolved, gives

$$x = a \pm \sqrt{a^2 - 1}.$$ 

From this expression, it appears that the problem is
impossible if $a$ be a fraction, positive or negative, be-
 tween the limits of $+1$ and $-1$, because then $a^2$
will be less than $1$, and $a^2 - 1$ a negative quantity, and
$\sqrt{(a^2 - 1)}$ an impossible quantity. However, if $a$ be
a positive quantity not less than $+1$, or a negative quan-
tity not greater than $-1$, (here we reckon $-2$ to be
less than $-1$, and $-3$ less than $-2$, and so on), the
problem will always be possible, and, excepting the cas-
es $a = +1$, and $a = -1$, $x$ will have two values, which
will be reciprocals of each other, because their product
is unity.

It also appears that the least positive value of the
expression $x + \frac{1}{x}$ is $+2$, and its greatest negative value
$-2$, reckoning, as before, that negative quantity to be
greatest, which, independently of the sign, is expressed
by the smallest number.

Hence, we learn that no real value of $x$ can be found
that shall make the expression $\frac{1}{2} \left(x + \frac{1}{x}\right)$ equal to a
proper fraction, either positive or negative, but that
this expression may represent any positive or negative
quantity whatever that is not between the limits of
$+1$ and $-1$.

From this example, it appears that the theory of im-
possible quantities may sometimes be applied with
great advantage to a very elegant and interesting class
of problems, namely, such as require the determination
of the greatest and least values of a variable quantity.
The general method of proceeding is to suppose, that
the quantity to be a maximum or minimum, is equal to
a given quantity; and then to inquire what is the
IMAGINARY QUANTITIES.

The greatest or least values which this quantity 1 can have, without introducing the imaginary symbol \( \sqrt{-1} \) into the resulting formula.

The second class of imaginary expressions, or those which indicate real quantities, involve the symbol \( \sqrt{-1} \) in such a manner, that, by suitable transformations, it may at last be made to disappear. The two following expressions are of this kind, viz.,

\[
\sqrt{(a + b\sqrt{-1})} + \sqrt{(a - b\sqrt{-1})} = \frac{1}{\sqrt{-1}} \left\{ \sqrt{(a + b\sqrt{-1})} - \sqrt{(a - b\sqrt{-1})} \right\}.
\]

By taking the square, and then again the square root of each, the former is transformed to

\[
2\sqrt{(a^2 + b^2) + 2a} \frac{1}{\sqrt{-1}} \left\{ \sqrt{(a + b\sqrt{-1})} - \sqrt{(a - b\sqrt{-1})} \right\},
\]

and the latter to

\[
2\sqrt{(a^2 + b^2) - 2a} \frac{1}{\sqrt{-1}} \left\{ \sqrt{(a + b\sqrt{-1})} - \sqrt{(a - b\sqrt{-1})} \right\},
\]

which are both real quantities.

The general expression for the roots of a cubic equation has the form

\[
3\sqrt{(a + b\sqrt{-1})} + 3\sqrt{(a - b\sqrt{-1})},
\]

when its roots are all real; but, unlike the two former, it cannot, by any means, be transformed into a real algebraic expression, consisting of a finite number of terms; but its value may be found by an infinite series, or a table of sines. (ALGEBRA, § 287—§ 289.)

It has been proved, in the Arithmetic of Sines, § 19, that, as being any whole number or fraction,

\[
\cos(x + \sin(x\sqrt{-1}))^n = \cos(mx + \sin(mx\sqrt{-1})).
\]

This formula was first given by De Moivre, (Phil. Trans. 1707, and Miscel. Analecta, lib. 2.) Lagrange calls it "a formula as remarkable for its simplicity and elegance as its generality and fertility in consequences," (Calcut des Fonctions, p. 116); and Laplace considers its invention as of equal importance with the binomial theorem, (Lettres des Ecoles Normalis. As the sign of the square root of a quantity may be either + or -1, we may put in the formula -\( \sqrt{-1} \) instead of +\( \sqrt{-1} \); it then becomes

\[
\cos(x - \sin(x\sqrt{-1}))^n = \cos(mx - \sin(mx\sqrt{-1})).
\]

From this, and the former expression, we find, by addition and subtraction, that the imaginary expression

\[
\cos(x + \sin(x\sqrt{-1}))^n + \cos(x - \sin(x\sqrt{-1}))^n
\]

is equivalent to 2 cos mx, or real quantity; also, that imaginary expression

\[
\frac{1}{\sqrt{-1}} \left\{ \cos(x + \sin(x\sqrt{-1}))^n - \cos(x - \sin(x\sqrt{-1}))^n \right\}
\]

is equivalent to 2 sin mx, another real quantity. These expressions, although the representatives of real geometrical quantities, viz. 2 cos mx, and 2 sin mx, considered by themselves, are utterly without any geometrical signification. It is impossible to translate the analytic formula into the language of strict geometry, because the symbols sin x \( \sqrt{-1} \) and \( \frac{1}{\sqrt{-1}} \) correspond to nothing that admits of geometrical definition. Notwithstanding this incongruity, these very expressions have led to the discovery of some of the most beautiful and general theorems in geometry, and have enabled analysis to resolve questions which, without their aid, would have been altogether untractable. We have given examples of their application to the theory of angular sections, and the investigation of that elegant property of the circle called the Cotesian theorem, in the Arithmetic of Sines, § 19—§ 23.

If in the formula

\[
\cos(x + \sin(x\sqrt{-1}))^n = \cos(mx + \sin(mx\sqrt{-1}) - \frac{1}{\sqrt{-1}};
\]

we write \( \frac{1}{n} \) for m, it becomes

\[
\cos(x + \sin(x\sqrt{-1}))^\frac{1}{n} = \cos(x\sqrt{n} + \sin(x\sqrt{n}\sqrt{-1}) - \frac{1}{\sqrt{-1}}.
\]

Suppose now n to be indefinitely great, then, x being supposed a finite arc, the \( \frac{1}{n} \) will be indefinitely small; in this case its cosine will be equal to the radius, and its sine equal to the arc itself, hence, \( \frac{1}{n} \) being indefinitely great,

\[
\cos(x + \sin(x\sqrt{-1}))^\frac{1}{n} = 1 + \frac{x}{n} \sqrt{-1},
\]

or putting \( \cos(x + \sin(x\sqrt{-1}))^\frac{1}{n} = v \),

\[
\frac{1}{v} = 1 + \frac{x}{n} \sqrt{-1},
\]

and hence \( \frac{1}{v^2} = x\sqrt{-1} \).

Now it has been demonstrated in the introduction to the article Fluxions, § 14, that n being supposed infinitely great, \( \frac{1}{v} = Nap. \log. v \), therefore

Nap. log. \( v = x\sqrt{-1} \)

and hence, c denoting the basis of the system, (ALGEBRA, § 285 and § 286) we have \( v = e^{x\sqrt{-1}} \), that is,

\[
\cos(x + \sin(x\sqrt{-1}))^\frac{1}{n} = e^{x\sqrt{-1}};
\]

This is another imaginary formula of great value, because it exhibits under a finite form a relation between an arc or angle, and its co-sine, sine, &c. It was first observed by Euler, and is justly regarded as one of the most important analytic inventions of the last century. Other investigations of this formula have been given in Arithmetic of Sines, § 19, and Fluxions, § 124. Observing, as before, that the square root of a quantity may be considered as negative as well as positive, we have from the formula,

\[
\cos(x - \sin(x\sqrt{-1}))^n = e^{-x\sqrt{-1}};
\]

and from the two expressions, by addition and subtraction,

\[
\cos x = \frac{1}{2} \left\{ x\sqrt{-1} - x\sqrt{-1} \right\} + e;
\]

\[
\sin x = \frac{1}{\sqrt{-1}} \left\{ x\sqrt{-1} - x\sqrt{-1} \right\} - e.
\]

These formulae, in their present state, are illusive; for the arc and sine, or co-sine, cannot, by means of them, be found, the one from the other. However, by expanding the exponentials into series, we have, (ALGEBRA, § 257.)

\[
e^{x\sqrt{-1}} = 1 + x\sqrt{-1} - \frac{x^2}{2} - x\sqrt{-1} = \frac{x^3}{12} - \frac{x^3\sqrt{-1}}{1.2.3} + \&c.
\]
IMAGINARY QUANTITIES.

The imaginary quantities are those which cannot be represented by a finite number of square roots or surds. The numbers which may be expressed by such roots are called real quantities. In the 17th century, John Bernoulli and others demonstrated the existence of imaginary quantities and showed that they could be used in calculations. They are useful in the study of complex numbers and have applications in various fields of mathematics and engineering.

For instance, the number $\sqrt{-1}$ is an imaginary quantity. By substituting it into the formula $e^{x\sqrt{-1}}$, we get $e^{x\sqrt{-1}} = \cos x + i\sin x$, where $i = \sqrt{-1}$. This is the famous Euler's formula.

One of the most important properties of imaginary quantities is that they can be added, subtracted, multiplied, and divided just like real quantities. However, division by zero is undefined.

Consider the fraction $\frac{a + b\sqrt{-1}}{c + d\sqrt{-1}}$. By substituting the trigonometrical formula, we get

$$\frac{a + b\sqrt{-1}}{c + d\sqrt{-1}} = \frac{r \cos \theta + i r \sin \theta}{c + d\sqrt{-1}}$$

where $r = \sqrt{a^2 + b^2}$ and $\theta$ is the angle between the line joining the origin to the point $(a, b)$ and the positive real axis. The expression can be further simplified using trigonometric identities.

In conclusion, imaginary quantities play a crucial role in mathematics and have many applications in various fields. They are a fundamental concept in the study of complex numbers and are used extensively in electrical engineering, quantum mechanics, and other areas of science.
IMAGINARY QUANTITIES.

I and the hyperbola (as will readily appear from Fluxions, § 150, Ex. 5.)

c = \frac{1}{\sqrt{e^2 - 1} \left( x - \sqrt{-1} \right) - \sqrt{-1}},

d = \frac{1}{\sqrt{e^2 - 1} \left( x - \sqrt{-1} \right) + \sqrt{-1}},

and in the hyperbola (as will readily appear from Fluxions, § 150, Ex. 5.)

c = \frac{1}{\sqrt{e^2 - 1} \left( x - \sqrt{-1} \right) - \sqrt{-1}},

d = \frac{1}{\sqrt{e^2 - 1} \left( x - \sqrt{-1} \right) + \sqrt{-1}},

These expressions are perfectly analogous in their form, so that if in the first set \( \sqrt{+1} \) be put instead of the imaginary symbol \( \sqrt{-1} \), it will be immediately transformed into the second. By the first set of formula, the whole theory of the Arithmetic of Sines may be investigated, and by the second, a corresponding theory relating to the co-ordinates of a hyperbola, many of the corresponding properties of the two curves will be identical, and some will differ only in the signs of the terms. In both, the results will be alike free from the imaginary sign, although in the one case the steps by which they have been found are unintelligible, and in the other, they are perfectly significant. This agreement of two methods so very different in the discovery of truth, the ingenious writer attributes to the analogy that takes place between the subjects of investigation, which is so close, that every property of one may, with certain restrictions, be transferred to the other. Hence it happens, that the operations performed with imaginary characters, although destitute of meaning themselves, are yet notes of reference to others which are significant: They point out indirectly a method of demonstrating a certain property of the hyperbola, and then leave us to conclude from analogy that the same property belongs also to the circle. All that we are assured of by the imaginary investigation is, that its conclusions may, with all the strictness of mathematical reasoning, be proved of the hyperbola; but if from thence we would transfer that conclusion to the circle, it must in consequence of the principle which has been just now mentioned. The investigation, therefore, in every case resolves itself into an argument from analogy, and after the strictest examination, will be found to have no other claim to the evidence of demonstration. A proposition that is proved of the hyperbola only, and afterwards concluded to hold true of the circle, merely from the affinity of the curves, will have precisely the same degree of certainty as when a proof is made out by imaginary symbols.

Of late years another theory of impossible quantities has been brought forward by M. Buce, in the London Phil. Trans. 1806, also by M. Argand, in a work with this title, Essai sur une manière de représenter quantités imaginaires dans les constructions géométriques, published in France in 1806, and again by M. J. F. Français in Nouveaux principes de géometrie de position et interpretation géometrique des symbol imaginaire, published in Annales de Mathématicques, Sept. 1813. According to these writers, the impossible character \( \sqrt{-1} \), is the sign of perpendicularity; so that the imaginary expresion \( a \sqrt{-1} \), instead of being the sign of an operation which cannot be performed, and which has no geometrical representative, is, according to these writers, represented geometrically by a perpendicular to a straight line: that is, if a line to the right be expressed by \( +a \), and an equal line to the left by \( -a \), then a third line perpendicular to and equal to either of these will be expressed by \( \pm a \sqrt{-1} \).

To prove this, the last mentioned writer defines the ratio of magnitude to be the numerical ratio between the magnitudes of the two lines and the ratio of position, the inclination of the one line to the other, or the angle they contain. Again he lays it down, that four straight lines are in proportion of magnitude and position, when between the two last there is the same ratio of magnitude and position as between the two first. That is, supposing \( a, b, c, d \) to be the magnitudes, we must have \( \frac{a}{b} = \frac{c}{d} \), also the angle contained by \( a \) and \( b \) equal to the angle contained by \( c \) and \( d \).

When the consequent of the first ratio is the antecedent of the second, the proportion of magnitude and position is said to be continued, and the middle term is a mean proportional of magnitude and position between the other two. From this it follows, that the middle term bisects the angle made by the two extremities.

These observations being premised, he gives the following theorem as the foundation of his theory. Imaginary quantities of the form \( \pm a \sqrt{-1} \) represent in the geometry of position perpendiculars to the axis of the abscissa, and reciprocally, perpendiculars to the axis of the abscissa are imaginaries of this form. For, putting \( +a \) and \( -a \) for straight lines lying in opposite directions, according to M. Français, the quantity \( \pm a \sqrt{-1} \) is a mean proportional of magnitude and position between \( +a \) and \( -a \). Now it has been premised, that a line, which is a mean proportional in magnitude and position between two lines, ought to bisect the angle they contain; therefore, in the present case, the mean must be perpendicular to the axis of the abscissa, and will lie above or below the axis according as it is \( +a \sqrt{-1} \), or \( -a \sqrt{-1} \). Reciprocally, every perpendicular to the axis of the abscissa must, according to the same principle, be a mean proportional between \( +a \) and \( -a \); it is therefore an imaginary quantity of the form \( \pm b \sqrt{-1} \).

Such is the substance of M. Français' demonstration; but to us it seems to be by no means satisfactory. We should have supposed, that in seeking the mean of magnitude and position between \( +a \) and \( -a \), he would have sought the mean of magnitude independently of position, and then the mean of position independently of magnitude. These would have required different operations; the first would have given \( \sqrt{a \times a} = a \) for the mean of magnitude, and, putting \( q \) for a right angle, the second would have given \( \frac{q(q + q)}{q} = q \) for the mean of position. We cannot, however, see any useful conclusion deducible from the result. The author of the theory, by calling the lines \( +a \) and \( -a \), seems to have invested them at once with magnitude and position. While at the same time he seeks the mean by a process, which applies to them as things having only magnitude.

The proof offered by Mr. Buce in support of the truth of the proposition, that \( \sqrt{-1} \) is the sign of perpendicularity, is not more conclusive. He supposes three equal straight lines to meet in a point, two of them to be in one straight line, and the third to be at right angles to them both. He calls the line taken to the right \( +1 \), then that taken to the left, he says, must be \( -1 \); and the third, which must be a mean proportional between them, must be \( \sqrt{-1} \), or more simply \( \sqrt{-1} \). Hence he infers, that \( \sqrt{-1} \) is the sign of perpendicularity. The inconclusiveness of this reasoning, has been well exposed by an able critic in the Edinburgh Review, vol. xii. July 1808, where it is observed, that any imaginable conclusion might have been derived in the same manner. For example, the third line, instead of being at right angles, may be supposed
It is bounded on the north by the principal chain of Caucasus, on the east by Georgia, on the south by the pachalic of Aghalzighe, and on the west by the Black Sea. It exceeds 100 miles in length from east to west, and is probably nearly as many from north to south. Imiretta is watered by the Ilioni and Kwarli, or Qurai-lia, said to signify the roaring rivers, besides numerous tributary streams, the course of most of which is interrupted by cataracts. The former rises in the mountains of Saami, and after being swelled by the waters descending from the hills of Georgia, falls into the Black Sea at Poti. The climate is extremely mild; snow seldom lies on the ground; and the rivers in the southern parts are never frozen over. Much of the surface consists of rocks and mountains, interspersed with fertile valleys and plains. Abundance of fruit of the finest produce—flavour grows wild, and without cultivation; and the trunk of the vine is known to attain 15 inches in diameter. Entire hills are overgrown with olive, chestnut, and valuable timber trees; and the lower grounds are full of almonds, quinces, pears, and plums, the latter sometimes bearing twice a year. Copious harvests of grain, as also of cotton, hemp, and flax, are obtained by the inhabitants, who likewise cultivate the quantity of silk that may be required. From the variety and abundance of fruit, this country has been compared to one vast orchard. Imiretta yields a kind of green honey, which possesses a highly intoxicating quality; and another very singular product called stone honey, or quastraph, by the natives, whose nature is imperfectly explained. It is described to be quite solid, as hard as sugar-candy, brittle, and not viscous. The honey and wax form one mass, generally of a white colour, but growing yellow with age. It is endowed with a pleasant aromatic flavour, and is found in the clefts of rocks. The Imirettians frequently carry it about with them in their pockets.

The population of the principality is computed at 20,000 families, whose personal appearance is superior to that of their neighbours. They are in general an indolent, distrustful, and proud, though servile, race; bold and fearless. They are distinguished by the virtue of hospitality; and travellers are always offered honey, fruits, and wine. Honey, among several of the Caucasian nations, forms a common ingredient of food, which occasions the cultivation of bees to a great extent in this country. The Imirettians are fond of dress and ornaments; they wear several cloaks at a time; and those who can afford it, ornament themselves with chains of gold and silver. But the larger portion, from indolence, insecurity, and other causes, are exceedingly poor, and even reduced to great necessities. They are dispersed in retreats on woody hills, by the sides of rivers or in valleys, courting solitude, it is said, in order to screen themselves from their enemies, as well as to be preserved from oppression. But they use certain calls or signals, by which, on extraordinary occasions, hundreds are collected in a moment, in places where no one could previously be discovered. As nearly the whole inhabitants dwell in solitary hamlets, the country contains scarcely any towns except Cotatis or Kuthais, the capital, situated on the right bank of the Phasis or Ioni, and Poti or Pori, on the left bank of the same river, at its eflux into the Black Sea. Cotatis seems to consist of somewhat more than 100 houses, chiefly inhabited by Armenian merchants, and is now in a state of decay. Poti is geographically situated within the confines of Mingrelia, and is not known to be larger than the former. In 1806 it was in the posses-

The natives of Imiretta are chiefly occupied in agriculture. Some thousands emigrate annually to Georgia, where they hire themselves out as servants or porters. The remainder manufacture good silkens stuffs and thick woolen cloths, but no linens. They make a kind of wine of superior quality to that of the countries in the vicinity, much of which is exported in skins to Georgia, and drank at Tiflis; and they also export grain, honey, and wax. All the commerce of Cootis is in the hands of Armenians, who carry their traffic as far as the Russian establishment of Moskow.

The Imiretians profess the religion of the Greek church; they have a patriarch, who is usually of the royal family, but who nevertheless can seldom read or write. Their churches are wretched buildings, with a paper cross over the principal entrance, and some paintings of the Virgin Mary and their saints within.

Imiretta is governed by a prince dependent on Russia, with which country it is now incorporated. He is styled Mephe, and is under the control of a national council, composed of the principal inhabitants, without whose consent he cannot undertake any important enterprise. The laws of Imiretta are founded on the will of the sovereign; but since the supremacy of Russia was acknowledged, he is deprived of the power of life and death. His ordinances were published on Fridays, the market days, by a cryer who ascended a tree, and thence issued the proclamation. Judicial combats are practised by the nobles, and the trial by water ordinal prevails. The revenues of the king amount only to between £5000 and £7000 yearly, which arise from a contribution of the peasants in wine, grain, and cattle; and from the tribute of neighbouring princes. By the census of 1803, it was found that 13,000 families paid taxes.

This country is said to be the ancient Iveria. At the conclusion of the fifteenth century it belonged to Georgia, when King Alexander divided it along with other states among his sons. It was afterwards subdued by the Turks, who were expelled by the Russians in the year 1779. About that period, Solomon, King of Imiretta, threw off the Turkish yoke, and sought the protection of Russia. He quelled the civil broil of his country, strengthened its interests, protected it against foreign invasions, and made many internal regulations, among which was the abolition of traffic in slaves. It is said that he ordered the walls and citadel of Cootis to be destroyed, observing that "the rocks of Caucasus were the only fortifications which were capable of being defended by an undisciplined army of 6000 men unperturbed with artillery." Solomon, after a prosperous reign, died in 1786. He was twice married, and appointed Giorgi, his son by the first marriage, to succeed him; but his reign was productive of tumults and dissatisfaction, and a civil war arose which terminated either by his death or deposition in a year. David, the son-in-law of Solomon, who had married a Georgian princess, succeeded to the kingdom, and reigned till 1793. Heracles, king of Georgia, desirous of securing his grandson Solomon on the throne, sent an expedition into Imiretta, whereby an insurrection was excited, and David expelled from the country, while his son Constantine was imprisoned in a fortress. After wandering as a fugitive several years, David died at Aghalaghe, a Turkish town of the Caucasian region. Meanwhile, the government of Solomon II. was confirmed; and in 1809, he conquered the province of Letschum. In 1802, Anna, the widow of David, and mother of Constantine, repaired to Petersburg, and obtained the liberation of her son, who had undergone a confinement of ten years. Solomon II., in order to secure himself in the government, acknowledged the supremacy of Russia in 1804; and he and his successors were declared the lawful sovereigns of Imiretta. Lat. 33° to 34° N. Long. 43° E. (c)

IMPEACHMENT, in law, is a mode of trying great and numerous offenders, or a presentment by the Commons of Great Britain, as the most solemn grand inquest of the whole kingdom, to the House of Lords, as the most high and supreme court of criminal jurisdiction. The method of proceeding is to exhibit articles on behalf of the Commons, who also appoint managers to make good their charges. The articles are then carried to the Lords, before whom, as judges, every trial by impeachment must be conducted. A commoner cannot be impeached before the Lords for any capital offence, but only for high misdemeanours. A peer may be impeached for any crime. No pardon under the great seal can be pleaded in bar of an impeachment by the Commons of Great Britain in parliament. See Court. (z)

IMPOSSIBLE QUANTITIES. See Algebra, and Imaginary Quantities.

IMPOTENCY, in law, or that corporal imbecility which renders a party naturally incapable of procreation, is a ground for annulling a marriage in the spiritual court. See Marriage.

IMPULSE. See Mechanics.

INCHKEITH, an island of the Frith of Forth, Early bistro, which derives its name from the Gaelic word Inuis, anerry island; and Keith, the title of a noble family of Scotland, to whom with other lands this island was gifted about the year 1010, by Malcolm II. for eminent services rendered by that family against the Danes at the battle of Barry in Angus-shire. The island afterwards came into the possession of the lords of Glamis in the reign of Robert II. along with the barony of Kingsbarns as part of the dowry of the King's daughters. From this period it appears to have passed through several hands, and came lately by inheritance into the possession of the noble family of Hecleck.

In the reign of King James the IV. a certain disease hospital had then been newly introduced into Scotland; in all this island probability from France. It first appeared about the year 1499, when it was thought to be so contagious, that the following order of the Privy Council was issued to the Magistrates of Edinburgh, viz. "That all manner of persons, being within the freedom of this burgh, who are infected of the said contagious plague called the Gangrene, devioli, rid, and pass forth of this town, and conpeper upon the sands of Leith at 10 hours before noon, and there shall have and find boats ready in the harbour, ordered to them by the officers of this burgh, readily furnished with victuals to have them to the Inch, (island of Inchkeith,) and there to remain till God provide for their health. And all other persons who take upon themselves to heal the said contagious infirmity, and take the care thereof, that they do not enter and pass with them, so that none of those persons who take the cure upon them, use the same within this burgh." The penalty of contravention, either by the diseased or their physicians, was burning on the cheek.

Such had afterwards been the deserted and seques-terated situation of this island, that James IV. in the course of his inquiries into the origin of language,
caused a singular sort of experiment to be made, by delivering two infants to the charge of a dumb woman, with whom they were sent to Inchkeith as the scene of their solitary confinement, till the children should reach a certain age. It would, at this day, have been somewhat interesting to have known the result of this experiment; but owing to the death of the king, and the troubles of the times, it seems to have been entirely lost sight of, and all that we now learn regarding it is, from Lindsay of Pitcaicott, who, in speaking of the children, observes, "Some say they spoke good He-
breui but as to myself, (he added, with proper caution,) I know not, but by report.”

During the period of the Reformation in Scotland, the Lords of the Congregation having applied to the English for assistance against the queen dowager, Mary of Guise, Edward VI. sent them a navy in 1549, consisting of 39 ships. The first object of this force was to have secured the port of Leith; but failing in this, they landed and took possession of Inchkeith. After rearing a temporary fort upon it, four companies of English, and one of Italians, were left for its defence, under the command of one Cotterell; who was soon afterwards attacked, and, after a very brave and gallant defence, was dislodged by the French auxiliary troops, then defending the town and citadel of Leith, under M. Desse, who seeing the importance of this island as a military station, from its commanding position, at a narrow part of the Frith of Forth, he saw its utility both as a cover to Leith, and a place of retreat in case of any sudden disaster. Desse had no sooner made himself master of the island, than the temporary works of the English were thrown down, when a regular fortification was erected, by order of the Regent, under the sanction of her daughter Mary and the Dauphin of France, her husband. This fort consisted of several strong bastions, laid out for the defence of the place, with a strong wall of circumvallation, varying in height from a few feet to upwards of 20 feet, according to the situation of the ground. The principal parts of this work, were executed in square or asiler masonry, and from the inaccessible nature of the island, either as to landing places or roads, it must in three days have been considered an operation of no small magnitude and expence. It seems also to have been regarded by the Scottish Parliament as a place of so much importance, and one which might be turned to so much account against the country by an enemy, that the works were only allowed to remain. It appeared state for a few years, when, by an act of that legislative body, the whole of the fortification, and the greater part of the walls were thrown down, excepting the eastern wall, and part of the southern wall, which still remains. The royal arms of Scotland is also preserved in one of the walls, with the initial letters M.R. and the date 1556.

Inchkeith lies, per compass, from Leith S. W. distant about 4 miles, and 3 miles from Kinnhorn in Fife. It contains about 70 acres; is of a long, and somewhat irregular figure, measuring about one mile in length, and one-fifth of a mile in breadth. Its shores are much chcterised with rocks, and indented with several small creeks or bays, capable of being converted into good harbour harbours. Its surface, though in many parts rocky, and throughout extremely irregular, yet, in general, is covered with a good sward of grass; while in the more sheltered points, the soil is not only deep, but so extremely rich that it produces the most luxuriant crops where cultivation has been attempted. It produced indeed such excellent pasture, particularly for horses, that while it was in the possession of the French, they called it "L'isle des chevaux." On the eastern and western sides, the island is precipitous and abrupt; while towards the north and southern end, particularly the latter, it rises more gradually, to the height of 180 feet, calculating from high water mark to the summit or site of the lighthouse.

Inchkeith possesses several pretty abundant springs of the purest and most excellent water that is any where to be met with; and since a boat harbour and landing pier have been constructed, the water has been collected in the higher parts of the island, and conducted by a leaden pipe, from a large stone cistern, to the harbour, where it is served out by the light-hour keeper. From this cistern the shipping in Leith roads is supplied, and seamen remark that this water is better, and keeps longer free of impurities, than any other with which they are supplied.

The rocks of this island belong to the coal formation, and are distinctly stratified upon the great scale. They consist chiefly of beds of trap-tuff, amygdaloid, slate-clay, bituminous shale, lime-stone, sand-stone, and green-stone. The lime-stone, in some places, is of a fibrous texture, somewhat resembling asbestos. On the south-west side of the island, under the lime-stone, there is a bed of flinty slate, containing the traces of madrepores and shells. Some very beautiful specimens of crystallized quartz are also found in various parts of the island; and detached masses of rock, much imbricated with iron. Nodules of agate are not uncommon on the shores; they have been washed from the amygdaloid rock, in which they occur imbedded. The stratification of this island has a south-western direction, dipping towards the east at an angle of about 45°. It is also worthy of remark, that the same strata of rocks, with a similar direction and dip, are observable on the Fifes shores to the north; and in the direction of a chain of sunken rocks extending towards Prestonpans, they have been traced on the south side of the Frith.

Besides horses and black cattle, which thrive well on this island, sheep are sometimes pastured here; but the grass is considered too rank for sheep. There is a pretty numerous tribe of the common grey rabbit here, which would increase and become very numerous were they not so much annoyed by occasional sportsmen visitors. An attempt has lately been made to introduce a species of the rabbit here, remarkable for the length and slickness of its hair. The sea swallow, or pictaryn, breeds on the island; and occasionally the elder duck makes its nest on the least frequented part of the shore. Since the erection of the light-house, birds of passage, particularly woodcocks, have been sometimes attracted by the light on stormy evenings, and have suffered themselves to be taken by the keeper. On one occasion, a number of beautiful small birds (fringilla flam-
men), having a tuft of crimson feathers on the back of the head, took shelter about the light-house. The grey Norwegian rat is pretty numerous on the island; no doubt brought here originally by the shipping in Leith roads. The fishes found in the neighbourhood of Inchkeith are chiefly of the smaller kinds, and such as are common to the Frith of Forth; particularly rock-
codling, pollack, or young coalfish, and small whiting. One peculiarity, or change upon the habits of the fishes in the Frith of Forth, which has been well authenticated by several of the oldest fishermen of the contiguous village of Newhaven, may here be noticed, viz. that in former times, alluding to a period about the middle of the 18th century, great numbers of large haddocks and whiting were caught above, or to the west-
ward of Inchkeith, but that such fishes are scarcely now to be found to the westward of the isle of May, 20 miles.
further to seaward; so that the Newhaven fishers are now almost entirely confined to their employment as pilots, or to the dredging for oysters. At present colling, holbub, large coalish, and skate, excepting at certain seasons, when the latter come up the Frith to spawn, are only to be met with in the deep sea as far off as the Bell-rock. To account for this change, the fisherden have the following theory: They suppose, from the much greater number of shipping which anchor in Leith roads, and the more frequent discharge of guns from ships of war, that the fish are prevented from resting on this ground. The number of seals, however, which haunt the sea-ribs in the neighbourhood of Inchkeith, is certainly not less, especially in winter, as '70 of these animals have been counted upon one rock by the writer of this article. The seals indeed may rather be supposed to have increased of late years, as the hordes which formerly played about the Bell-rock, have almost entirely deserted it since the erection of the lighthouse on that rock.

The importance of the safety, and facility of the navigation of the Frith of Forth, will best appear by viewing this great estuary under the principle laid down upon the eastern coast of Great Britain, that ships in the North Sea can fly for refuge in storms of easterly directions. Independently, therefore, of this Frith opening the way to so great extent of commercial coast from the Red-head in Angus-shire, on the north, to St. Abb's-head in Berwickshire, towards the south, with which its shores are bounded; it is, in fact, a matter of the greatest national importance to open the way, by proper land-marks, for the direction of the mariner to Leith roads, as a safe anchorage at all times of tide, and in all states of the weather. For it often happens, when the riding of ships is no longer safe or practicable in Yarmouth roads, and when the river Humber and Cleerness Frith are inaccessible, the Frith of Forth being now lighted and guarded nearby at all points, lies quite open for their reception.

The Light-house Board, aware of the advantages of the navigation of the Frith of Forth upon general grounds, proceeded to its improvement as their funds would admit; and these not being at first adequate to the much more expensive works of the Bell-rock, commenced with the lighthouse of Inchkeith, forming an island peperd to guide to the roads of Leith. Upon an application being presented from the Trinity House of Leith, on the 18th May, 1803, the foundation stone of this useful building was laid, and the light exhibited on the evening of the 1st of September 1804.

There was no built pier or landing place, nor any road upon the island for the conveyance of heavy materials to the size of the building; and if such had existed in the early state of this island, which is indeed more than probable, they had been entirely destroyed along with the works of the fortifications, as not the least vestige of these works remained, or could be traced in 1803, when the light-house operations were begun. So completely was this an "unfrequented coast," to speak in the language of Dr. Johnson, that the light-house artificers were actually obliged to lodge in a cavern in the rocks, near the south-eastern part of the island, until they could rear a temporary barrack on the top of the island, near the ruins of the fort.

Hitherto the erections of the Light-house Board had been confined simply to two apartments for one light-keeper; and, from the inmost state of the fund, the first lighthouses were more of a temporary nature, to answer the immediate purpose of the shipping; as the whole of the coast of Scotland, excepting the Isle of May, was in darkness, or without the aid of light-houses, at the commencement of the institution of the north light-houses.

When the works of Inchkeith, however, were undertaken, the funds being in a more prosperous condition, instead of two small apartments for a single light-keeper, the plan of the houses was now extended to the accommodation of a principal and an assistant light-keeper, who now keep a constant watch, by night, in the light-houses, in the same manner as is done on ship-board, when a vessel is at sea; and the whole establishment is now more like the appointment of a public board. The dwelling house at the light-house stations, instead of exposing, as formerly, a long slated roof on a house of one floor, is now built, as at Inchkeith, with two stories, or floors, and covered with a leaden roof. On the same substantial plan the light-houses are constructed; for instead of the roof of the light-room being framed with timber, and the windows glazed with crown-glass, that of Inchkeith is composed of copper, and the windows are glazed with polished plate glass, of much larger dimensions; and the whole premises are, in a great measure, rendered fire-proof, the floors being all covered with pavement, or with stones, from the quarries near Inchkeith. The building operations at Inchkeith were greatly facilitated, and rendered much less expensive, from having the use of the stones of the old fortification and walls, which had been thrown down by an act of the Scottish Parliament. The stones of the old fort had been quarried, and taken from a bed of sandstone on the island; and the remains of those old quarries are still observable, both upon the south-west and eastern sides of the island.

In the original design of Inchkeith light, it was meant to have been built upon the plan of a double, or leading light, by the erection of a second light-house, upon the precipitous rock facing the westward; and, by keeping both lights in a line, ships were to have been enabled, under night, to pass the narrow channel, between the island of Inchcolm, and the dangerous rocks called the Oxarans; but this part of the plan has never been put in execution.

When the present light-house was completed, it was appearance what seamen call a stationary, or fixed light, and con. of the light remained 16 reflectors, made up the parabolic curve, formed of copper, strongly coated or plated with silver, instead of the hollow, or cavity of the reflector, being lined with facets of mirror-glass as formerly. Inchkeith light remained as a stationary light till the year 1815, the period when the light of May was altered from an open coal fire, to a stationary light, with oil and reflectors; and it became necessary to alter the character of Inchkeith light, from a stationary to a revolving light, agreeably to its present appearance; and, with this alteration, seven reflectors, instead of the former number, are now found perfectly sufficient. The machinery for making the light revolve, consists of a movement, or piece of strong clock-work, kept in motion by a weight, and curiously fitted with two governors, upon the plan of the steam engine, instead of a fly wheel. The reflectors are ranged upon a horizontal frame, which is made to revolve periodically, upon a perpendicular axis, exhibiting, to a distant observer, the alternate effect of light and darkness, in a very beautiful and simple manner. The reflectors are brought round in succession to the eye of the observer, and the angles, or interstices between them, produces the effect of darkness, by which this light is distinguished from the light of the Isle of May, and also from the numerous surrounding lights on the opposite shores.

It is further of importance to remark here, that the
light of Inchkeith is elevated above the medium level of the sea about 295 feet; and such is the powerful effect of the reflecting apparatus, that it is distinctly seen in a favourable state of the atmosphere, at the distance of four or five leagues, although it is impossible that more than a single reflector can be seen at a time.

The elevation or design of this light-house is considered to be in very good taste. It is a house of two stories, with a platform roof, and parapet with embrasures; the light-house tower forming the staircase to the second floor and light-room. The light-keepers are very comfortably lodged, the principal having three apartments, and his assistant two. Besides the main house, a court of offices is formed in connection with the eastern wall of the old fort; and, besides other conveniences, there is an oil cellar sunk under ground, in which the oil is always kept in a fluid state, and at an equal temperature. There is also a place fitted up without the gate, as a watch-house for pilots, where they have a guard and fire-place.

This establishment is in all respects very complete, and the situations of the light-keepers rendered pretty comfortable. The principal has a salary of £45, and his assistant £35; besides 10 acres of the island inclosed, and a garden, which they possess or hold in common, with a sufficient allowance of coal and oil for family use.

The following inscription is cut upon a stone, in a conspicuous part of the building: "For the benefit and security of commerce, and for the direction and comfort of mariners, this light-house was erected by order of the Commissioners of the Northern Lighthouses. It was founded on the 16th of May, 1803; and lighted on the 1st of September, 1804. Thomas Smith, Engineer." Under our general article Light-house, we shall have occasion to treat more fully of distinguishing light-houses. See Fitecott's History; Sibbald's Fife; Pinkerton's History of the Stuarts; Arnot's History of Edinburgh; Dr. Johnson's Tour, 1773. (s.)

INCOMBUSTIBLE CLOTH, is the name of a species of cloth which resists the action of fire. It has been known for many centuries, that a mineral substance called asbestos can resist the action of fire; and that some species admit of division into fine slender threads of a lanuginous appearance. These in general are very short and brittle, but with careful attention in the separation, they may be obtained several inches in length. The ancients, availing themselves of the peculiar property of asbestos, devised means of working it into cloth, Pliny and Dioscorides, speak of asbestos cloth nearly in the same terms. Pliny in one passage remarks the incom bustible nature of asbestos; and in another he speaks as if he had actually seen napkins made of it, which, being thrown into the fire during entertainments, were much better cleansed and came out whiter than if they had been washed with water. Dioscorides says, that "cloth is prepared from the asbestos of Cyprus, which, being thrown into the fire, burns, but is unconsommed, and comes more splendid from the flames." Besides the preceding observation, Pliny adds, that from this property the cloth was used to preserve the ashes of kings when their bodies were committed to the funeral pile. We find occasional allusions to asbestos cloth ever since the age of Pliny; and the ingenuity of mankind in our own era has proved that it may still be made of the same materials. Accordingly, Isidore, who lived in the 7th century, observes, that from asbestos, "something mechanical has been framed by human art." A chemist of the ninth century describes the process of making it, which proves to be very near the truth; Marco Polo, Simon Majolus, and a few others, testify its existence subsequent to the darker ages; after which Kircher, Ray, Ciampini, and many more, directed their attention towards its substance and manufacture. The words of Pliny concerning the use of incom bustible cloth in preserving the remains of princes, are thought by some commentators not to apply to the Roman sovereigns, but to those of the east; and it is said that a Tartar prince sent a piece of it to Alexander, one of his popes. Marco Polo, who travelled into Tartary in the thirteenth century, speaks of a province called Chinchinthalas, in which a substance is found whereof incom bustible cloth is made. He learned from "Curfican, a very intelligent Turk, that the process consists in drying it in the sun, and beating it in a mortar, after which it is washed and wrought like wool. It is to be put during an hour into the fire, when it comes out whiter than snow; and no other washing is required, if dirty, than passing it through the flames." Caecilius Rhodiginus only makes an allusion to incom bustible cloth, but Simon Majolus saw an incom bustible cloak of asbestos exposed to the fire at Louvain; and Agricola observes, that at Verulam in Saxony there was another of the same substance. Kircher tells us, that in his museum he had a whole cabinet full of asbestos articles; that he had got a napkin of it from Cardinal Lugo, which after being thrown into the fire came out quite clean. He also had writing paper of the same substance, from which the letters were entirely obliterated on being committed to the flames, as if washed out, and the paper was withdrawn entire and clearer than before. Thus, he observes, correspondence could constantly be carried on by means of a single sheet. In addition to these instances may be mentioned the information of Mr. Ray, to whom the Prince Palatine shewed an incom bustible purse at Heidelberg, which received no injury after being thoroughly ignited in a pan of charcoal. A long rope likewise, which had been steeped in oil, and then put into the fire, proved incom bustible. In the year 1702, a funeral urn was found, containing a quantity of bones and ashes, wrapped in a piece of incom bustible cloth no less than eight feet long, and five in breadth. Being presented to Pope Clement XI, he ordered it to be deposited in the Vatican, where it yet remains, and affords incontrovertible evidence of the truth of Pliny's narration. Some of the monkish writers also inform us, that a certain St. George being sentenced to be burnt alive, he was enveloped in asbestos cloth, that they might not ascribe his preservation from fire to a miracle.

Pliny is silent respecting the mode of fabricating asbestos cloth. The chemist of the ninth century directs the alternate soaking of asbestos in oil and water, in order to render it fit for spinning. Kircher, in the seventeenth century, affirms, that there were a few persons in his country acquainted with the mode both of spinning and weaving it, whereas some specimens might be seen in his museum; but such individuals were very rare, and did so only with the view of great emolument. He considered it a secret art; adding, that though it had been described by Boetius, Libavius, and Vorta, they had been deceived by an erroneous account. Pivati, in his Encyclopaedia, published in the year 1748, says, that a quantity of asbestos was formerly spun at Venice. All these remarks refer to an early date, and they inspired very little confidence. At length Ciampini, an
INCOMPRESSIBLE CLOTH.

Italian, entered on a course of experiments towards the beginning of the eighteenth century. The method he describes consists in soaking the asbestos in warm water, after which it is opened and divided with the hands, to allow the extraneous particles to escape. This operation being frequently repeated, the flaky parts are collected and laid in a sieve to dry, and then gently carded, some of the flaxen substance being allowed to hang over the sides. Next, by mixing the ends of thread with what hangs over of the asbestos, both may be drawn out and twisted together, and wound on a reel. Or, instead of carding the substance and then using thread, Ciampini affirms that the asbestos may be drawn out by mixing it with common hemp. During the operation, the fore finger and thumb must be kept constantly wet with oil, both to protect the skin from the friction of the substance while drawing out in a thread, and to render the filaments more soft and flexible. The thread of asbestos, combined with real flax, having been thus obtained, it may, with great care, be woven into a coarse cloth; which, being put into the fire, the flaxen portion will be consumed, while the asbestos portion remains entire. This cloth can be best preserved by keeping it well oiled; when committed to the flames, the oil burns off, and the cloth comes out white and purified. Whether or not the art was preserved in Europe, there is every reason to believe that it subsisted in the East. Independent of the Venetian traveller's narrative, we learn, that a piece of incompressible cloth was transmitted from China to Batavia, and from thence to England, in the year 1684, which is described as a handkerchief or pattern, but it seems to have been a small portion of very coarse cloth. It was subjected to various experiments, and the result was, its being withdrawn whiter and cleaner after having been rendered red hot in a fire.

A few years ago, the art of making incompressible cloth was completely revived by M. Ferpertini, an Italian lady, who has improved on the process of all her predecessors. Having seen a distaff of asbestos, from the ruins of Herculanum, in the cabinet of natural history belonging to the canon Cesar Gattioni at Como, she was made acquainted with him, with the different methods of spinning, and the ancients are supposed to have adopted in making cloth. On inspection, also, she remarked, that their asbestos cloth was fabricated of double threads, in order to be of greater strength. M. Ferpertini began by beating the asbestos, and steeping it in oil and in water, whereby the threads became more pliant; but finding them too much relaxed for weaving by the oil, she abandoned this method. She restricted her operations to softening it in water, drying it in the sun, and then carding it like wool. A very close toothed steel comb was used in carding, as the filaments were thick and short; and in this way she succeeded in obtaining a weak and unequal thread, with which nevertheless she was able to make a pair of gloves. Much difference, however, is to be found in the nature of the asbestos itself. Ciampini had before remarked, that although the asbestos of Cyprus is reputed the best, it in fact proved the worst; and what was most suitable came from Corsica. M. Ferpertini first used asbestos from the mountains of the valley of Malentum and the Valteline, which proved to be better than what was procured from the environs of Genoa. In the former, she observed, there were threads much longer than the piece of asbestos containing them: whence it became important to devise some method whereby they should be detached and unravelled. Here also M. Ferpertini was successful, for by rubbing the asbestos, and disengaging the two ends of the threads, she thus obtained some of the greatest beauty, and suitable for the most delicate work. These were several feet long, and equally fine and strong as silk or linen thread. It was the more singular that such should be the case, as a piece of asbestos, to external appearance, exhibits only a mass of thick short threads, which has always been the chief obstacle to the fabrication of incompressible cloth. All the previous preparation therefore which is necessary, is confined to softening the asbestine substance in water, beating it to create greater flexibility, and employing the iron comb. The threads acquire greater consistence, by moistening the finger with a little oil or gum while they are spun.

Incompressible paper. Those who have occupied Incompressible themselves with the subject of incompressible cloth, materials have also directed their attention to the fabrication of incompressible paper from asbestos. Kircher proposes a certain process for it, which we do not discover he adopted. Some which was made of Welsh asbestos towards the close of the seventeenth century; and Ciampini thinks the shorter asbestos threads would answer this purpose. M. Perpenti found the asbestos of Genoa, which was less suitable for spinning, the best adapted for making paper, which she accomplished by washing and purifying it. Some time ago, M. Sage exhibited before the French Institute, a leaf of incompressible paper, made twenty years before that period by M. Levrier of Lisle, the proprietor of a paper manufactory. It was not smooth like paper fabricated of flax, but had sufficient coherence, and, if the ink employed was well gummed, would readily receive writing. When put among burning coals it was not consumed; it assumed a greyish colour from the glue, and the written characters appeared red. M. Sage regret that M. Levrier had not received greater encouragement, as deeds of common paper might be preserved from the flames by inclosure in cases of that of asbestos; but Ciampini remarks, that it was more adaptation to a stick which was made of asbestos and enveloped in it. According to M. Perpenti's experiments, an indestructible ink may be obtained, by mixing a third of sulphate of iron with two-thirds oxide of manganese, the whole being well pulverised.

The Chinese and Siberians are said to have gone farther than any modern nation in converting incompressible substances to use. M. Sage describes a small furnace, constructed by the former, of a kind of card or paper, which, in his opinion, consisted entirely of asbestos. It was nine inches high, six in diameter, and provided with a grate, and two doors for the ashes. The colour was grey tending to red, but whitened with heat. Both externally and internally it had a smooth polish resembling pasteboard, and its fracture was absolutely similar. M. Sage conceived, that the asbestos having been pounded, was mixed with a mucilaginous paste, which being put into a mould, thereby acquired its shape and polish.

Besides incompressible cloth and paper, the ancients are supposed to have possessed the secret of making perpetual or inextinguishable lamps, apparently with the same materials. Several tombs have been opened, which the spectators declare contained burning lamps, though many centuries had elapsed from the sepulture of the deceased. Isidorus relates, that a candelabrum was reported to be in the temple of Venus, which neither wind nor rain could extinguish. We believe that directions have been given for constructing perpetual lamps: but the experiments of the moderns with asbestos do not appear to have been successful, for oil would not rise in the wick. It is most likely, however, that
INCUBATION.

This is a mistake; for oil ought to rise in asbestos as well as in other wicks. Yet this would only be gaining an incombustible wick. The ancients however affirm, that asbestos once heated never cools, which has probably been the source of other opinions that it may constitute a perpetual lamp. See Pliny Hist. Natural. lib. xix. cap. 4. xxxvi. cap. 31; Dioscorides, lib. v. cap. 158; Isidorus Orig. lib. xvi. cap. 4; Kircher, Mund. Subterraneus, vol. ii. van leeuwen Rhodiginus, Lect. Antiq. lib.xiv. cap. 31. M. Pauli Veneti de Regiomontis Orientalibus, in Grynaeus Novus Orbis, p. 325; Vancrullus de Rebus per Perboetis: Philosophical Transactions, vols. xiv. xv. xxii. xxvii. li. Bell's Travels, vol. i.

INCUBATION is that instinctive process by which birds sit unremittingly upon their eggs, with the exception of short intervals employed in quest of food, until by imparting their vital warmth, the young acquires sufficient strength, and breaks the shell.

Persons not conversant with natural history have believed, that life does not exist in the egg until the commencement of incubation, or the application of artificial heat. The effect of either does no more, however, than unfold the latent germ. About 10° of heat are required to hatch the eggs of our common domestic poultry, which, in hens, must be continued during 21 days. Sometimes the period is longer or shorter, ranging between 19 and 23. The period required by the eggs of other birds is extremely diversified; whence Count Morazzo has inferred, that the period of incubation is proportional to the duration of the life of the bird; in the same way as he conceives the gestation of mankind and quadrupeds is proportional to the length of their existence. The swan, which is supposed to live 200 years, sits 42 days; the goose, supposed to live 80, sits 30; while the goldfinch, whose life is restricted to 18 or 20 years, does not sit on its eggs above 14 days.

The experiments of most observers have been made on the eggs of the common hen; but Malpighi did not confine himself to these exclusively. On inspecting an egg at the larger end, where all the changes take place, several conspicuous parts appear, as the albumen, the yolk, the air vessel, and the membranes, besides some which are less obvious; but the highest magnifier is incapable of discovering the germ of the chicken. Nothing more than a confused whitish spot, generally called the cicatrix, is discernible. Malpighi, indeed, who has treated this subject under a microscope, a manner in which he seems to affirm, that the embryo is perceivable before incubation, but it has been sensible to no other observer. He likewise thought its evolution would be seen in six hours after incubation, and has given a magnified delineation of the appearances. Haller considers it unnecessary, at least in the climate of Switzerland, to make observations previous to seven hours; and he remarks, that Malpighi's egg of six hours was as far advanced as his of twenty-four. On the whole, it is to be concluded, that none of the more evident changes happen before the twelfth hour. At that time a slight enlargement of the cicatricula is found to have taken place. The embryo, still of the most irregular and indistinct figure, has undergone some expansion; it is surrounded by a line of a greenish or deep yellow colour. The rings or haloes environing it, of which sometimes three and sometimes four are visible, seem defined. No alteration is yet perceivable on the bulk or consistence of the fluids, though Haller says that an egg, with seven hours incubation, contains a greater quantity of albumen than it will ever have afterwards. A cavity at the large end, called the folliculus aeris, is full of atmospheric air, which is gradually enlarged by incubation; and although twenty-one eggs newly laid, afford only a cubic inch of air, the same quantity is yielded by two after twenty days.

Considerable alteration will be found to have taken place in twelve hours more, or after the interval of a day, from the commencement of incubation. The egg is surrounded by the small end downwards, by the enlargement of the cavity, or escape of its own fluids, and the figure of the embryo is better defined. It seems about .18 of an inch in length, whereas in 12 hours it does not exceed .1. The circles or haloes are more extended, and the interior one has acquired some resemblance to the figure of a heart, surrounded by a line of a greenish colour. Green specks are likewise perceptible in different parts of the area enclosed by it, which are the rudiments of blood vessels. Twelve hours later, the greenish line has gained more evidently the appearance of a vessel, and some of the specks are seen to contain blood. They are distinct blood vessels in two hours longer, and convey red blood in six more. In 48 hours, the foetus exhibits signs of motion. Its head resembles a hammer, and the tail is extremely slender. The vascular area has attained the figure of a heart, and pulsation is now evident, or perhaps some hours earlier. Still it appeared like a close and melted under the seal. At this period also the eyes become visible; and the contents of the yolk bag have grown somewhat more fluid. It was only at this time that Haller succeeded in measuring the length of the embryo, which proved .22 of an inch in one egg, and .20 in another. It must not be supposed, that there is the most distant resemblance between this shapeless body and a bird; on the contrary, no two objects can be more dissimilar. At the end of 70 hours, the rudiments of the wings, and sometimes those of the legs, may be traced; and at the close of the third day, or 72 hours, the changes are still more conspicuous, and the parts better defined. Before the fourth has come to a conclusion, the pulsations of the heart are so tremulously rapid, that the eye cannot follow them. But as the life of the embryo is enfeebled by exposure to the air, they become retarded, and are seen to follow each other in regular succession. The liver is perceptible before the fifth day, not of its ultimate hue and aspect indeed, but as a viscous cloud of a yellow colour; and the eye also appears black; the limbs have not yet moved against its termination, nor has it gained its proper formation, and the viscera are unfolded. On the sixth day life is so vigorous, that it is not uncommon to find the chicken lying on its back, instead of on its left side as before. The natural figure is in a considerable degree acquired; and most of the organs exhibit a certain definite formation. The weight of the egg has now greatly diminished, the external colour darkens, and the substance of the shell becomes more brittle. Next day the white is smaller, and has sunk towards the small end of the egg, while the dimensions of the yolk are enlarged. From this period, the size of the animal advances with great rapidity. Its members are gradually unfolded, and its strength progressively increased. The muscular nature of the stomach is declared on the eleventh day. On the twelfth the albumen is seen to have attained a greenish hue, and to have acquired greater consistence; the chicken has gained a more perfect form; its head is greatly curved, and the bill lies under the right wing. It is pointed, and is sometimes opened and closed. On the nineteenth, half the egg is occupied by air, and the chicken is heard to cry. In the next place, the shell be-
comes extremely fragile, and towards the close of the twentieth day is generally cracked, but not, as erroneously supposed, by the mother. After this the chick is always heard, its beak projects, and, before the full period of incubation being completed, it is liberated from its confinement on the twenty-first. Now the albumen has totally disappeared, and the contents of the yolk bag occupy the abdomen, which is observed to be greatly distended. See Harvey Opera. Malpighi De Formatione Pulli in Ovo. Appendix de Ovo Incubato. Maitrejean Observations sur la Formation du Coeur dans le Poulet. Halle sur la Formation du Coeur dans le Poulet. Journal de Physique, vol. iv. p.480. Transactions of the Linnean Society, vol. x. Rees' Cyclopædia, vocæ Incubation: (c).

History. INDEPENDENTS, one of three leading denominations under which all Protestant Christians may be classed, in as far as regards their tenets on the subject of church-government. They are generally considered as having derived from the Brownists, but may be said more correctly to have been founded as a distinct religious community about the year 1610, by John Robinson, a man of acknowledged piety and learning, who officiated as pastor of a small congregation in Leyden, and who first published a declaration of their principles in 1610, under the title of, Apologia pro conditibus Anglii, qui Brownstone volgo appellatur. After his death, a number of his hearers, having obtained from James I. a promise of full liberty of conscience in America, removed thither with their families in 1620, where they founded the colony of New Plymouth, and became the parents of the independent churches in that quarter of the globe. The first independent society in England was established in 1616 by a Mr. Jacob, who had adopted the sentiments of Robinson; but the severity of the penal laws against nonconformists in those times prevented the principles of this community from attracting much public notice, or making any considerable progress, till about the year 1640. From that period they increased rapidly both in number and reputation. Among the various causes which contributed to this success, must doubtless be admitted the distinguished learning of many of their teachers, and the general sanctity of their members. They enjoyed also the peculiar protection and patronage of Cromwell, whose favour could not well fail to augment the number of their followers in those days, but whose prelucdion for their tenets, perhaps, contributed not a little to draw upon them afterwards much undeserved obloquy. Instead of accounting for this friendly disposition of the Protector, by the supposed congeniality of their principles with republicanism, (of which, in fact, he had certainly become the enemy and subverter,) it may be ascribed, with just as much show of reason, to the circumstance of his apprehending, from their limited union, less danger of any powerful counteraction to his despotic views, than from the more systematic forms of the Episcopal and Presbyterian church policy. This growing influence and estimation of the independent name, king whatever cause it may have been owing, induced the greater part of the religious sectaries of that period to assume the same denomination, though neither always adhering to the principles nor possessing the respectability of the genuine independents. After the restoration of Charles II., their cause greatly declined; and, in the year 1661, after the accession of William III., they entered into an association with the Presbyterian dissenters in England, by which they seem to have in some measure departed from the original principles of their sect, and to have conformed in many points to the sentiments of their new allies. Since this period the greater part of the different dissenting societies in England have, on their part, adopted the leading principles and practices of the independents on the subject of church government, even though maintaining very opposite tenets on doctrinal points. But still the independents, properly so called, form a distinct and flourishing society, and have well conducted academies, for the education of their young ministers, at Homerton, Hoxton, and Wymondley-house, near Hitchin.

In Scotland, about the year 1728, Mr. John Glass, a minister of the established church, formed a separate community, which bears his name, and holds the fundamental views of the independents. About the end of the 18th century, Robert Haldane, Esq., collected in the same country several congregations, which conform rather more closely to the English independents; and, in consequence of his own changes of sentiment, and various other causes, the greater part of these societies were soon disunited and dispersed. A few of the more respectable teachers, who had concurred in the general views of Mr. Haldane, have continued to follow the plan of the English independents, and are attended by considerable congregations.

The independents evidently derive their name from their leading principle in church government, namely, that every Christian congregation ought to be governed by its own laws, without being subject to the jurisdiction of any other ecclesiastical authority. Robinson expressly uses the term in explaining his doctrine on the head of church government, in these words, "...a certain quæmlibet particularæm, necesse institutum et ordinatum, esse totam integram et perfectam ecclesiam, et suis partibus constantem, immediate et independentem, (quod alias ecclesiam), sub ipsa Christi, &c., and it is not improbable, that from this very passage the designation was originally derived. It was publicly assumed by the English independents in 1644, in a publication entitled, Apologetical Narration of the Independents; but, in process of time, when a number of turbulent and discordant sects, as already mentioned, had begun to arrange themselves under this extensive denomination, the proper independents became desirous to substitute in its place the name of Congregationalists, or congregational brethren.

From the Brownists, with whom they have often Tenets of being improperly confounded, they differed considerably in many important respects. They were much less uncharitable towards other churches; and while they regarded their own form of ecclesiastical government as peculiarly resting on apostolic authority and example, yet they candidly acknowledged, that true religion might flourish in those communities, which were under the jurisdiction of bishops or presbyters. They were more attentive in maintaining a regular ministry, and excluding promiscuous teaching in their societies. In regard to doctrine, it appears from "A declaration of the faith and order, owned and practised in the congregational churches in England," published in 1658, that in no point of any importance did they differ from the Presbyterian Calvinists. "Protestor coram Deo, hominibus, aede nobis convenire curm ecclesias reformatas Belgicis in re religionis, ut omnibus et singulis eorumde ecclesiarum fidei articulis, ut habitet in harmonia confessionum fidei, parati subscribere—Ecclesi

2 Those our readers can scarcely fail to recollect, are Episcopalians, Presbyterians, and Independents.
fession of the congregational brethren to be agreeable to the said rule. The IX., relating to the duty and deportment of the brethren towards those that are not in communion with them, inculcates charity and moderation.

It is argued by the independent writers in support of their principles, that the word εὐαγγελιόν, usually translated church, is always used in Scripture to signify either a single congregation, or the place where a single congregation is assembled; that, wherever there were more congregations than one, there were more churches than one; that though the whole nation of Israel is called a church, yet, as having but one place of worship, first the tabernacle, and afterwards the temple, it formed no more than a single congregation; that the Catholic church of Christ is likewise a single congregation, having one place of worship, namely, heaven, where all the members assemble by faith and hold communion, and where they shall be all finally gathered together as one glorious assembly. They farther insist, that the principle of congregational churches is confirmed by the practice of the primitive church; that the disciples in Jerusalem, though certainly numerous before they were dispersed by persecution, are never mentioned as forming distinct assemblies, but as meeting in one place; that after their dispersion, they no longer read of them as one church, but as the churches of Judea, Samaria, Galilee, Galatia, Macedonia, Asia; but that whenever the disciples of a particular city, who might ordinarily assemble in one place, are spoken of, they are uniformly called a church: as the church of Antioch, the church at Corinth, the church of Ephesus, &c. That, in all these churches or congregations, there were elders or presbyters and deacons, who all laboured in word and doctrine, but none who merely assisted in ruling or governing, they argue from Acts xiv. 23, xx. 17; and that these office-bearers did nothing, of common concern to the church, without the consent of the multitude, they hold to be deductible from Mat. xviii. 15, &c. Acts vi. 1. xv. 22. xx. 23. 1 Cor. v. 3, 4, 5. Rev. ii. 2. In regard to the ordaining of elders or pastors in a particular church, they reason, that the ordinary and permanent officers of Christ's appointment do not succeed those that were extraordinary, such as prophets and apostles, in any thing peculiar to their work; that what these inspired teachers were to the disciples of their time, their writings are to us; and that no man can now be called to the ministry of the word otherwise than that word directs; that the character, qualifications, and duties of those who should exercise the office of elders in the church, are completely delineated in the New Testament; and that, as far as concerns this description, it is not competent for any man or body of men to add or detract; that whoever possesses these qualifications or characters, and is chosen by the congregation, has all the call and mission that is requisite, and can receive no new powers whatever from the ordination of a bishop or a presbytery.* See Mosheim's Ecclesiastical History, v.; Neale's History of the Parians; Hoornbeek, Summa Controversiarum Religionis; Glass's Works; Ewing's Attempt towards a Statement of the Doctrine of Scripture on some disputed Points respecting the Government, Worship, and Discipline of the Church of Christ, a work which at once ably advocates its principles, and frankly impugns the abuses to which they are liable; and Brown's Answer to Independency, the most complete view of the arguments on the opposite side. See also Presbytery, in which will be given also a view of Episcopal as contrasted with the other distinguishing systems of church government. (q)
In this article we mean, in the first place, to give an abstract of the history of India from the earliest period till the year 1760, when the Mogul dynasty was in fact reduced to insignificance, and the Europeans, particularly the English, began to assume the greatest influence in Hindostan; in the second place, we shall give a sketch of the rise and progress of the European settlements in India; and this will lead us to a continuation of the history of Hindostan from the year 1760 to the present time: and, lastly, we shall give the statistics of India.

I. History. When the Greek and Roman writers mention India, in the most extensive acceptation of the term, they include a space as large as the whole of Europe, comprising an area of 40 degrees of latitude and longitude. They regarded it as bounded on the west by the Arachosian mountains, which divided it from Persia; on the east, by the Chinese part of the peninsula beyond the Ganges; on the north, by the deserts of Tartary; and on the south, by the line. Within these boundaries lay the hills of Tibet; the valley of Cashmere; all the territories in which the ancients placed the Indo-Scythians, Nepal, Bootan, Assam, Camaroon, Siam, Ava, Aracan, and the adjacent kingdoms as far as the China of the Hindoos, and the Sin of the Arabian geographers; the entire western peninsula of Hindostan; and the island of Ceylon.

According to the Mahomedan writers, the territory in immediate subjection to the sovereigns of Delhi was understood. This was divided, in the year 1382, by the emperor Acher, into eleven spots, or provinces, viz. Lahore, Multan in which Sinde was included, Ajmeer, Delhi, Agra, Allahabad, Bahar, Oude, Bengal, Malwa, and Guzerat; Cabul, and the countries lying to the west of the Indus, formed a twelfth spot; and when the Decan was conquered, three new spots were added, viz. Berar, Khandesh, and Aurungabad.

It is evident, that the limits assigned to Hindostan by the Greek and Roman writers are not only much too extensive, but they are also very vague and indefinite, and those assigned by the Mahomedan writers, being derived from and varying with the extent of the conquests of their sovereigns, are on that account unsatisfactory. The limits assigned by the original Hindos are, on the contrary, extremely well defined. According to them, Hindostan is bounded on the north by the Himalay mountains, which commence near the Indus, in about the 35th degree of north latitude; and extend from Cashmere without interruption beyond the eastern extremity of Hindostan; this limit on the north includes the hilly districts of Nepal, and the country belonging to the Deb Rajah of Bootan; on the west, the river Indus is the natural boundary; and on the south, the ocean; on the east, the Hindoos point out the eastern hills and forests of Tipperi and Chittagong as the boundaries of Hindostan; these will carry their country nearly as far as the 90th degree of east longitude. Hindostan is thus defined by natural limits, and its extent and boundaries are pointed out almost as accurately and clearly by another circumstance; for within the natural limits the primitive Brahminal religion and languages prevail, with the exception of Bootan; nor are they found beyond these limits, except in Assam and Cassay. It was called Bharat-veereshe, or Bharata, by its ancient inhabitants, from Bharat, one of the nine brothers, whose father, according to the Brahmins, ruled the whole earth, and to whom this portion of the globe was assigned. To these names they sometimes prefixed the epithets of Medhyama, or central, and Punyabhumı, or the land of virtues. The word Hindostan, by which the Persians designated all that part of the empire that lies between the Indus and the Ganges, and the latitudes of 21° and 30° N., is derived from the words Hindoo, black, and stan, place; and the word Decan, which they applied indiscriminately to the whole of the southern peninsula, is derived from the Persian word deccan, south.

Hindostan, fixing to it the limits assigned by the Hindoos, is divided into four large districts. 1st. Northern Hindostan. This comprehends Cashmere on the west, and Bootan on the east; on the south, it is bounded by the first ridge of mountains, that rise from the plains of Delhi, Oude, Bahar, and Bengal; and on the north by the Himalay ridge, which divides it from Tibet. 2d. Hindostan proper comprehends the eleven provinces formed by the Emperor Acher already mentioned. The Nerbuddah river divides it on the south from the Decan. 3d, Decan is bounded on the north by the Nerbuddah, and by a line drawn from its source to the mouth of the Hooghly. The Krishna and Malpurba are the boundaries on the south. This division comprehends the provinces of Aurungabad, Khandesh, Beder, Hyderabad, Nandere, the northern Circars, Berar, Gundwana, Orissa, and great part of Bejapoor. 4th. The south of India extends from the Krishna to the ocean, and comprehends a small part of Bejapoor; the Balghaut ceded districts; the three Carnaties, terner, central, and southern; Mysore, Canara, Malabar, Bararamahal, Coimbeotoor, Dindigul, Salem, Kistnagherry, Cochin, and Travancore.

In the present article, we shall confine ourselves, both in the history and statistics, to the second, third, and fourth divisions of Hindostan, referring our readers to the articles Cashmere, Nepal, and Tibet, for information respecting the first division; and to Bengal, Canara, Carnatic, Malabar, Mysore, and Travancore, for more particular information respecting the principal provinces in those parts of Hindostan of which we shall here treat.

The traces of the ancient chronology and history of India are very faint and imperfect, and are nearly quite lost in remote antiquity. It is supposed by those Europeans who have made the most elaborate and careful researches on these points, and who have investigated, and compared on the spot, the features, manners, languages and religions of the various tribes who inhabit this vast territory, that a few only of the aboriginal inhabitants are to be found scattered in the hilly countries; and it is certain, that the Brahmins have traditions that their ancestors came from the north, and having conquered Hindostan, established there their customs, religion, and languages. According to them, Bharata comprehended ten kingdoms or states, each speaking a different language; five of these were called Original inhabitants.

The ten kingdoms of ancient Hindostan.
Gauras, occupying the northern and eastern parts of India; and five were called Draviras, extending from Cape Comorin to Guzerat. The first state of the Gaurus, comprehended all the Punjab, as far west as the Indus, and south as Guzerat: it was called Sareswata from the principal river. The dominions of the Cannayacchhas, a warlike nation, comprehended part of the province of Delhi, Oude, Agra, Surangur, and probably Allahabad and Cashmere. Tribut extended from the Cusi to the Ganges, and from the Ganges to the mountains of Nepal. Bengal extended over the province of Bengal, and probably part of Bahar. Uteala extended along the shores of the Bay of Bengal, from Balasore to Godavery, and inland as far as Samapoor. Dravira proper extended from Cape Comorin to between 12 and 13 degrees of north latitude. North of Dravira, was the kingdom of Carnatic; it occupied part of Myso-re, the Carnatic, and the shores of Coromandel: its name may be traced in the Carnatic on the east, and Canara on the west coast. Tailingana extended over the country between the Krishna and Godavady. The country of Muru or the Maharashtras, now called the Maharattas, occupied the district to the south of the Ner-budda, and the maritime country of the Kocan or Khandeish. Gurjara, the modern Guzerat, seems not to have changed its ancient limits. At what period these ten great kingdoms of Bharata were formed, or when they were mingled and redivided, is not known; but many centuries before the Mahomedan conquest they had changed their names and relative importance. About two thousand years before the birth of Christ, Bharata comprised four rich and powerful kingdoms, together with many subordinate principalities. According to the Puranas, or ancient books of the Hindoos, which treat of the creation, and of the genealogy of their gods and heroes, these kingdoms acknowledged as their common head, the sovereign of the most powerful of them, with whom they all united for mutual defence against foreign invasion, and under whom, in time of war, they acted. At all other times, and in every other respect, they were separate and independent states. The kingdom of the Prachii, or Prasii, people of the east, was the most opulent and powerful: it comprehended the modern provinces of Bengal, Bahar, and part of Oude. The kingdom of Bejanagur, which ranked next that of the Prachii, comprised the whole of the great Peninsula, from the Krishna to Cape Comorin. The third state extended from the Gulf of Cambay to the mouths of the Ganges, and from the latitude of 22° to 17° north. The provinces of Lahore, Multan, Delhi, and Ajmeer, constituted the last of these kingdoms. The sole management of the internal police of all these kingdoms belonged to the rajas of the several provinces, into which they were divided; but these rajas were tributary and responsible to their respective sovereigns.

The only events in the history of Hindostan, prior to the birth of Christ, of which we possess any direct and clear information, either from the Greek and Roman authors, or from the ancient books of the Hindoos, are the great war of the Mahabharat, the invasion of India by Sesostris, and by the Persians in the reign of Darius Hystaspes; and the transactions of the reign of Chandra Gupta, the contemporary of Alexander the Great.

The era of the war of the Mahabharat can be fixed with considerable precision and accuracy: the heroes of that war are expressly declared in the Hindoo books to have been contemporaries with Pararsara, in whose time an observation of the place of the solstices was made, from which it appears that he lived 1591 years before Christ. This war was carried on by Krishna and his Brother Bali Rama, against Jara Sandhub, who reigned in Magadha, and was distinguished by its cruel and by the decisive and permanent political and religious changes which it produced. The brothers having surprised their adversary in his capital, Rajagriha, caused him to be split asunder. The ancient worship of Siva, or Maha Deco, was nearly annihilated, in order to introduce that of Vishnu Hercules, Krishna; those who still adhered to the ancient religion were compelled to flee to the mountains, while the political as well as the religious followers of Krishna took possession of the plains. At the period of this invasion, there existed in the kingdom of Magadha, several warlike tribes, called Xetries; by these Krishna was not only sternly resisted, but his newly established power was rendered insecure by their activity and turbulence. In order, therefore, to give security and stability to his conquests, the Xetries were actually exterminated in many of the provinces, and Sudras and other low castes elevated in their stead. After the murder of Jara Sandha, Bali Rama placed Sahadevati, the son of Jara, on the throne of his father; but his authority was little more than nominal, as Bali retained for himself the greatest part of his conquests; the extent of these may be inferred from the circumstances, that within his own territory, he built or restored Palipota on the Ganges, Mahaballipooram to the south of Madras, and Pali Pur in the Deccan; and that Gada, another brother of Krishna, was raised to the sovereignty of the country called after him Gadipoor, or Gaziapor, while many other provinces were bestowed by Krishna on the principal of his followers.

Though it has been found so extremely difficult to fix the era of Sesostris, and to free his history from events evidently either fabulous or highly exaggerated, that many authors have been disposed totally to deny its authenticity; yet it appears to us that no reasonable doubts can be entertained that he invaded India. The circumstances of this invasion, the causes which gave rise to it, and the objects which he had in view, cannot be ascertained; but we are expressly informed by Diodorus Siculus, that he crossed the Ganges, and advanced as far as the Eastern Ocean. His conquests, however, were not permanent, and indeed were so contrary to the genius and habits of the Egyptians, that, on the death of Sesostris, they were entirely relinquished.

The Persians under Darius Hystaspes obtained a firm, though a less extensive empire in India, than the Egyptians. That monarch having subdued the countries which lie in a south east direction from the Caspian to the Oxus, turned his thoughts towards India, on which they bordered. In order to prepare himself for this new enterprise, he appointed Scylax to explore the Indus and the country lying on its banks, from the upper part of its navigable course to its mouth. The account which Darius received from Scylax of the populousness, fertility, and high cultivation of this territory, incited the Persian monarch to aim at its conquest. This he appears soon and easily to have accomplished; but his conquests did not extend beyond the district watered by the Indus; and of the circumstances attending them, we are entirely ignorant. It would seem, however, that he compelled some of the Indian princes to acknowledge his dominion, by the payment of an annual tribute; for we learn from a Hindoo writer, that the ostensible cause of the celebrated invasion of India by Alexander the Great, was to levy this tribute,
which some of its princes had refused to pay, and to
compel them to acknowledge their dependence on the
throne of Persia.

It would appear, that the extensive confederacy form-
ed in Hindostan, by the mutual understanding and the
union of the four great kingdoms already mentioned,
against foreign invasion, did not last long. Before the
conquest of the Persians, dissensions had risen among
the different states, which, together with the wealth of
the people, and their unwarlike character, invited the
invaders not only of these conquerors, but also of the
fierce and destructive barbarians of Tibet. By them
the northern provinces were attacked and laid waste.
It appears also, that foreign war, instead of producing
domestic concord, extended and heightened their mu-
tual animosities; so that, at the period of the invasion
of India by Alexander the Great, the nations of the pe-
ninsula were totally separated from the kingdom of the
Prachhi, though the western provinces of Hindostan
were more closely connected with it than at any for-
er period.

It is highly probable, that this union of the western
provinces enabled them to make such a vigorous de-
defence against the enterprise and high military skill of
Alexander, as to enable the much superior discipline of his
troops; that their defence excited his surprise and ad-
miration, we are expressly informed by Arrian, Plu-
tarch, and other historians; but their efforts, though
roused to religious enthusiasm by the eloquence of the
Brahmins, were ineffectual. Alexander, after having
subdued several small states on the banks of the Indus,
passed the different rivers of the Punjab, attacked Por-
rus, the sovereign of that district, who had collected a
numerous army to oppose his march, and obtained a
decisive victory, in spite of the gallant defence of that
prince, who, together with some of his most distin-
guished generals, was taken prisoners. This battle
was fought on the banks of the Hyphasis, which river
it was necessary for Alexander to cross, in order that
he might reach the Ganges, the great object of his am-
bition. To this point he now resolved to push; but
his troops had already done so much, and suffered so
greatly, especially from excessive rains and incessant
mudstains, that their patience as well as their strength
were exhausted, and they unanimously refused to ad-
ance farther. Alexander tried every effort, but in
vain, to change their purpose; they were inflexible,
and the conqueror was obliged to give way to his
troops, to abandon all his favourite schemes of farther
conquest, and to issue orders for marching back to
Persia. This memorable mutiny took place on the
banks of the Hyphasis, the modern Beyah, one of the
most celebrated rivers of the Punjab. Alexander left
behind him some of his most experienced officers, with
a small part of his army, for the purpose of keeping
possession of the conquered territory on the banks of
the Indus; but his troops gave way to every kind of
corruption and debauchery, to which they were stimu-
lated by the policy of the Hindoos; mutual animosities
and recriminations took place; and the death of Alex-
ander, which happened about this time, hastened the
downfall of his power in Hindostan. It was not, how-
ever, immediately annihilated. Pytho, the son of Age-
nor, seems to have succeeded to some part of Alexan-
der's Indian conquests; and Seleucus, who obtained
Upper Asia on the death of his master, considering
those countries of India, which had been subdued by
Alexander, as belonging to that portion of the Mace-
donian empire of which he was now sovereign, marched
into it, partly with a view of establishing his own au-
thority there, and partly in order to curb Sandracottus.

Sandracottus, called by the Hindoo writers Chandra
Gupta, was descended from the ancient lunar kings of
Magadha, but he was illegitimate, his mother having
been the daughter of a barber. His father was Nanda,
king of the Prachhi, of whom the Hindoos relate so
many wonderful stories. Sactara, his prime minister,
murdered him in his old age, but was in his turn put
to death, with the whole of his family, except one son,
by Upadhanwa, the son of Nanda. The young man,
however, who had been spared, watched for an oppor-
tunity of revenge, and having provoked Upadhanwa
to offer an affront to a Brahmin, he took advantage of
the confusion occasioned by the consequent excom-
munication of the king; and associating himself with
Chandra Gupta, entreated the assistance of the neigh-
bouring monarchs to overturn the kingdom of the
Prachhi. Of these monarchs, the one who could afford
the most ready and effectual assistance, from the contigu-
ity of his territories and his power, was Parvateswara,
lord of the mountains, king of Nepal; to him one-half
of the territory of the Prachhi was promised. This
monarch not only assisted Chandra Gupta with his
own troops, but also procured the help of the Yavans
or Greeks. Their efforts, aided by cruelty and treach-
ery, were successful; Chandra Gupta was seated on
the throne of Prachhi, but he soon forgot his promise
to Parvateswara. The new monarch put to death all
the noble and legitimate children of his father. His
reign, however, though commenced with these acts of
scarcity, seems to have proceeded in a manner much
more creditable to his character; for he was respected
abroad, and beloved by his subjects. Towards the
western princes he was more grateful for the assistance
they afforded him in obtaining his throne, than he ap-
pears to have been to the sovereign of Nepal. At
least it seems probable, from the accounts both of the
Greek and Hindoo writers, that the invasion of India
by Seleucus, about A. C. 300, was occasioned by Chandra
Gupta having offered his assistance to the western
princes against the neighbouring dominions of the Mace-
donians. The particulars of this invasion are ob-
scurely and differently related. According to some
accounts, Chandra Gupta marched a formidable army
to the banks of the Indus, and having restored the con-
quered provinces to their rightful masters, offered bat-
tle to Seleucus, which that prince declined. According
to other accounts, particularly those of the Greek his-
torians, the expedition of Seleucus was splendid and
successful. It is probable, however, that no decisive
success was gained by either party; and the terms of
the treaty, by which intuitions were concluded, seem
to confirm this conjecture. By this treaty, Seleucus
gave his daughter in marriage to Chandra Gupta, who
in return agreed to furnish Seleucus annually with fifty
elephants. In order to keep up and confirm more com-
pletely a friendly intercourse between the two mon-
archs, Seleucus sent Megasthenes, one of his officers,
a man of considerable acuteness and information, to re-
side at Baliputra, the capital of Prachhi. Daimachus
was afterwards sent as ambassador to Allitrochidas,
the son and successor of Chandra Gupta. The time and
manner in which the possessions of the Greeks in In-
dia were finally and completely wrested from them,
are not known, but it is probable that they were obliged
to abandon that country soon after the death of Sele-
cus. About 179 years after the invasion of this mo-
narch, however, Antiochus the Great made a short in-
We now arrive at a period of the history of Hindostan, not only of great interest and importance, but which is also made known to us in a much more ample and distinct manner than the events which preceded it; we allude to the Mahomedan conquest of that country. The first attempt of the Mahomedans to conquer India, was made during the reign of the Kalif Omar, A.D. 636, but it failed of success. In the reign of the Kalif Walid, the conquest of Sind was accomplished. Before this time, the Kalif Ali had sent a general, who effected some trifling conquests on the confines of this country. But, after long and bloody conflicts, he was forced to desist. As soon as the Kalif Walid had achieved this important conquest, the incursions of the Mahomedans into the fertile countries of Hindostan became more frequent and successful. They did not seem, however, to have attempted permanent conquest till nearly two centuries after they had obtained possession of Sind, the first Mahomedan prince who made a serious impression on India having been the Sultan Mahmood Sebecktaghin, who reigned at Ghazna. The empire of Ghazna was founded by Abistaji, governor of Khorasan, who rebelled from the king of Bucharia. His successor Sebecktaghin, the father of Mahmood, appears to have meditated the conquest of the western part of India. He actually carried his arms across the Indus, and ravaged the Punjab; but he made no establishments there, for at the period of his son Mahmood's invasion, a prince of the Brahmin race possessed the whole country along the east side of the Indus as far as Cashmere, his allies being the kings of Delhi, Ajmeer, Canoge, and Callinger.

These Mahomedan princes, though really independent, were however nominally subject to the Kalif; and even Mahmood, on his accession to the throne, received the robe of honour, and the investiture as sultan, from the Kalif Cadero, in the year A.D. 998.

Before Mahmood began his first expedition into India, he extended his empire northwards by reducing Bucharia, and he also obtained possession of Balk, or Balich. Three years after his accession, he entered Hindostan; but he remained only a short time in the year A.D. 1002, when he invaded Segestan. In the year 1005, he again entered Hindostan, and seized on Habeth and Multan. But he was again induced to leave his newly acquired territory, in order to turn his arms against Ik Khan, who, taking advantage of his absence, had besieged Balk. Such was the activity and success of Mahmood, that in 1006 he had slain the invader of his kingdom, and driven his army across the Oxus. As soon as he had secured his territories, he returned to India, under the united influence of ambition and religion; for true to the spirit and express commands of Mahomet, his object was no less to make conquests than to extend his dominions. His conquests, however, for some time were not very extensive; for in the course of eight years he made no further progress than to Multan. The inhabitants of this district, who, according to Major Rennell, were the Malli and Catheri (that is, the Kuttry or Rajput tribe) of Alexander, inheriting the martial spirit of their ancestors, opposed for so long a period such formidable armies, headed by so furious an enthusiast. In 1008, all the Hindoo princes, from the west of the Ganges to the river Nerbudda, were confederated against Mahmood; but they were at length defeated; and the victor's first step towards the destruction of the native religion, was the demolition of the famous temple of Nagore Cote, in the
The last of his dynasty, A.D. 1128.

Dynasty of the Gaurides.

mountains adjoining the Punjab country. His sixth expedition took place in the year 1011; in this also he was successful, and true to his religion, he again took advantage of his success to destroy Tannatar, a place of Hindoo worship, on the west of Delhi; the city of Delhi itself was taken at the same time. In the year 1018 the conqueror sent him back laden with his gifts to his own capital. He died either in the same year in which he took Khosru Shah prisoner, or in the year immediately succeeding.

Hassan was succeeded by his son Mahomed Seifudein; no event of moment occurred during his reign, but the joint reigns of Gaiadhotin Abuluffuthe and Shahbodien Abul Muzzaffur, which lasted 40 years, and the period of four years, during which the latter survived his brother, fixed the Mahomedan empire within India proper on the throne of Delhi. The history of the immediate cause of the revolution which overthrew the ancient Hindoo monarchy of India, Patti, or Delhi, is among the most romantic that even the annals of the East present.

"Jya Chandra, emperor of India, whose capital was Canoge, was not in truth the legitimate sovereign of the country: that title belonged to the young hero Pithaura, king of Delhi, whose noble character and unhappy fate are the theme of both Mussulman and Hindoo writers; the two monarchs appear, however, to have lived for some years in good intelligence, till upon occasion of a solemn sacrifice at the capital of Jya Chandra, where the functions of officiating priests were to be performed by sovereign princes, Pithaura, not choosing to perform an inferior part, while his rank as superior lord should have made him high priest, absented himself from the ceremony, and thus incurred the enmity and persecution of the monarch of Canoge. Shortly afterwards a more romantic adventure terminated not only in the destruction of Pithaura, but in his own ruin. Jya Chandra had adopted as his daughter a beautiful and accomplished damsel, whom the king of Sinhala Dwipa, or Ceylon, had presented to him, during an excursion he had made to that island under pretence of a pilgrimage, but in reality to extract tribute from the kings of the southern provinces. This damsel he had promised in marriage to a neighbouring monarch, but she being enamoured of the noble and valorous Pithaura, refused her consent. Pithaura being at that time at Delhi, and hearing of her affection, disguised himself, his brother, and attendants, as the servitors of a bard whom he sent to the court of Jya Chandra; and having by this means obtained an interview with the fair prisoner,—for such she had been since her avowal of her affection for Pithaura,—he carried her off in safety to Delhi, during a species of tournament held by Jya Chandra, though not without a combat, which deprived him of some of his bravest warriors. The king of Canoge, in order to revenge himself more completely for this insult, implored the assistance of Shahbodien, who accordingly marched with a powerful army against Pithaura, who roused himself from the delights of his capital, and the indulgence of his love, to meet the Mussulmans in the plains of Thanesar, where he was defeated and slain A.D. 1194. His capital immediately fell, and Shahbodien fixed in it the first and greatest of the Mahomedan monarchies in India; and very shortly afterwards overthrew Jya Chandra himself, and thus obtained the most extensive and richest provinces of Hindostan."
tion excited by his treachery in betraying the young prince Ali Shah into the hands of his rival on the throne of Khaoresm, Mohammed Shah, being murdered in his bed, A.D. 1212. He appears to have been an active and enterprising prince, and extended his territory considerably. He perpetrated in Benares the same cruel intolerance as Mahmoud Sebecbtagh had done at Nagore Cote, and Soumenat. He also carried his arms to the south of the river Jumnah, and took the fortress of Gwalior. He likewise extended the eastern part of Ajmeer.

The death of this emperor occasioned a new division of the Ghaznian kingdom. The Persian part became subjeet to Eldaze, and the Indian part to Cottub, who founded the Pan or Afghan dynasty in Hindostan. The latter was a native of Afghanistan, and originally a slave. He had been purchased by the emperor, whose notice he soon attracted by his talents and fidelity. As soon as he ascended the throne, he changed the seat of government from Lahore to Delhi, which was nearer the centre of the new conquests. The object of his immediate ambition seems to have been the reduction and annexation to his dominions of Bahar and Bengal; but his premature death saved them for a short period. The emperor Altmush, who ascended the throne of Delhi, A.D. 1210, was more fortunate, as he completed the conquest of the greatest part of Hindostan. He appears to have been the first Mabo- medan who reduced Bengal under his power; the government of which was from this period bestowed on one of the reigning emperor's sons. In A.D. 1215, he had nearly subdued all the kingdoms and principalities in Hindostan proper; his empire extending from the mountains of Tibet to that part of the Deean which lies in the latitude of 20° North, and from the Indus to the Ganges. He appears to have been a spirited as well as a judicious prince; and it is surprising, if we consider the principles and spirit of the Mahomedan religion, and the conduct of his predecessors, that there is no proof of his having persecuted the Brahmins, or destroyed the Hindoo temples. He appointed governors to the different provinces, and established and wholesome regulations for the guidance of their conduct. The natives of Bengal neither made much resistance to his conquests, nor endeavoured to throw off his yoke; but the robust and hearty mountaineers of Ajmeer and Malwah, as well as the inhabitants of Guzerat, still continued to oppose his authority, and seized with avidity and zeal every opportunity to assert their independence. Hence these provinces were almost constantly the scene of insurrections, which it sometimes required the whole power of the emperor to subdue. During his reign, the insurrections in the western part of his dominions also were very frequent and formidable.

The emperor Altmush was contemporary with the celebrated Gengis Khan. It was in the year 1221 that this conqueror reduced to subjection, and annihilated the dynasty of Charsam, which had sate for some time on the throne of Ghazna. Mohammed Shah at this period sate upon the throne, and he claimed also the dominion of some part of India: but, in consequence of having provoked the rage of Gengis Khan, he had not the leisure nor the means to secure his Indian territories. The lieutenant of Mohammed, in his province of Transoxania, had seized and put to death some Tartar merchants, who were travelling in a caravan from the camp of Gengis Khan. The Mogul monarch immediately sent to demand an apology, which was imprudently refused. The consequence was, that he immediately invaded Khoresm, which Mohammed had conquered in a single battle in the year 1199, and in spite of the valour displayed by the eldest son of the emperor, the troops of Mohammed were obliged to give way. At first the flight of the emperor was towards India; but, being intercepted, he was compelled to flee towards the Caspian Sea, in an island of which he died, A.D. 1220. His son fought long and valiantly, but without success, against Gengis Khan. One of his most desperate exploits was the swimming across the Indus in sight of the conqueror and his army. Five years afterwards he returned to Persia, and was for a short time successful; but he was at length obliged to yield to the better fortune of his opponent. By the year 1231, Gengis Khan had over-run all Asia to the northward of the latitude of 30°; but the difficulties he experienced in repressing the turbulent spirit of his Tartar subjects, very probably deterred him from attempting the conquest of Hindostan; though, in the year 1222, he had become the nominal sovereign of the empire of Delhi, and actually subdued all the country on the west side of the Indus, and portioned it out among his favourite generals.

In the short and fickle reigns between the death of Altmush and the elevation of the Emperor Balin, the Mogul chieftains made several predatory incursions into the Punjab; and Turmsheer Khan is reported by Sirefeddin, the historian of Timur, to have carried his arms into the Doob, and to have penetrated even to the confines of Delhi. Ferishta, however, does not mention the progress of this desultory conqueror, but only describes the inroads of the Moguls into the Punjab, which now frequently happened. In the year 1235, Feroze reigned at Delhi; he did not, however, long enjoy his dignity; his sister, who was a woman of great intrigue and activity, and of wonderful beauty, having gained over the chief of the nobles, drove her brother into exile, and took possession of his throne. She, however, in her turn, was exposed to intrigue, and being obliged to flee from her capital, she was killed in endeavouring to escape from her other brother Baharam, who was then raised to the throne. His reign also was of very short duration; for in little more than two years his army rebelled, and placed a son of Feroze on the throne; but he being a man of very weak abilities, was almost immediately deposed in favour of his uncle Nassurdien Mahmoud, a man of great energy, enterprise, and prudence, as well as of considerable literary attainments. For some time before he became emperor he had been imprisoned, and during his imprisonment he supported himself by writing, saying, that those who would not gain their bread by their labour, did not deserve to eat. Even after he was seated on the throne, he continued to supply his private wants by his own industry. He was eminently successful in all his wars, and astonished his subjects by the moderation and clemency with which he pursued his conquests. He died after a prosperous reign of twenty-one years, and, leaving no children, was succeeded by Balin, who was of the same family.

Balin had been originally a Turkish prisoner, who was sold as a slave to a person at Delhi; here making his fortune and proving his relationship to the reigning family, he was admitted into the highest rank and privileges, even before the death of Mahmoud. The character of Balin is represented as excellent in almost every point of view. It was one of his highest gratifications to make his palace an hospi-
table asylum for the oppressed and unfortunate, and at one period he entertained and supported twenty of the unfortunate sovereigns, whom the irruptions of the Moguls had driven from their dominions. He employed immense sums in encouraging trade and manufactures, and in patronizing the fine arts; and invited men of talents and literature from the most distant parts of Asia to reside at his court. Every night a society of poets, philosophers, and divines, met at the house of his eldest son; and over this society the poet Khasru presided. The patronage of the fine arts was more expressly the care of his younger son. The emperor himself encouraged magnificence in architecture, equipage, and dress, but he disowned the drinking and debauchery of every kind. As his claim to the throne was rather doubtful, there were frequent insurrections against him, and he is accused of having punished the authors of them in the most cruel manner, it having been remarked that he never pardoned a traitor.

In the year 1298, he appointed his eldest son vice-roy at Lahore, where his court became famous for its elegance and learning. When Belin was 80 years of age, the Moguls made a violent incursion into Multan, which the emperor sent his son to repel; in this enterprise he was slain, and his father died soon afterwards. At the time of his death, his second son Kera, being absent in his viceroyalty of Bengal, Key Kobaal his son was placed on the throne of Delhi; but after a reign of three years, he was murdered A.D. 1289, and Feroze the Second, an Afghan chief, was raised to the sovereignty. Properly speaking, he was of the tribe of Chiligi; but as the terms Panan or Afghan are applied in a loose manner to all the tribes bordering on the common frontiers of India, Persia, and Balk, he is included in the Panan dynasty. Although he was 70 years of age when he ascended the throne, yet he almost immediately projected the extension of his dominions by conquest. To this he seems to have been excelled by his nephew Allodin, a man of the most restless and inatiable ambition. Alla was governor of the town of Ghaznah, which was carried on the Decan; it may be proper, however, to mention that at this period, by the Decan was meant the country lying generally to the south of the Nerbudda and Mahanuddy, or Cuttack rivers. This country nearly equalled in extent the dominions of Feroze; for they stretched from the shores of the Indus to the mouth of the Ganges, and from the northern mountains to Cuttack, Si- rong, and Ajmeer, the greatest part of Malwa, and the Guzerat and Sind, being then independent. Alla having learned that the king of Deogir, the present Dowlatabad, one of the states of the Decan, was immensely rich, communicated this circumstance to the emperor, and represented the facility of obtaining his riches, and conquering his territories. This roused the covetousness of Feroze, and war was agreed upon. Alla, being appointed to conduct it, made an irruption into the Decan; his first expedition was attended with the capture of Deogir, and with it an incredible quantity of money and jewels. As soon as Alla gained possession of these, he increased his army, and marching back to Delhi, deposed and murdered the emperor of the strongest fortresses of the Rajpoots in Ajmeer; this was the first time that the latter fortress had fallen under the power of the Mahomedans. In the year 1303, he conquered Warangole, the capital of Tellingama, another principality of the Decan, comprising nearly the whole of the present district of Golconda. But while Alla was pushing his conquests in the south, he suddenly called upon to defend his own capital against the Moguls, who laid siege to it with a powerful army, and even plundered the suburbs; he arrived at Delhi just in time to save it from destruction; and after one of the most obstinate and bloody battles that is recorded in Indian history, he utterly defeated the Moguls, who with great difficulty effected their escape across the Indus. In the following year the remainder of Malwa was conquered; but the continual and sudden irruptions of the Moguls rendering the presence of the emperor necessary in the northern provinces, the conquest of the Decan was assigned to Cafoor, an able and enterprising general. He proceeded to the Deogir county, by the route of Baglana, which he reduced in his march; and not only carried his arms into Deogir, and from thence into Tellingama, but into the Carnatic also in the year 1310. By the Carnatic is here meant the Peninsula in general, lying to the south of the Krishna river. How much farther he penetrated into the south of India is not accurately known, but he was instructed by Alla to reduce Maber, by which Major Rennell understands the southern part of the Peninsula. The conquered countries were divided into provinces, over each of which Cafoor appointed a Ma- homedan governor. The quantity of treasure which he collected almost surpasses belief; it is said that silver was regarded by the soldiers as too cumbersome, and that they would not load themselves with any thing but gold: according to Ferishta, the treasure taken amounted to 100 millions sterling; the princes of the Decan had been employed in amassing it for a great number of years, so that it is probable their country had remained undisturbed all that time. In the year 1312, Alla again ravaged the northern part of the Decan, and exacted fresh tribute from Tellingama and the Carnatic; as, however, his expeditions were rather of a predatory nature, agreeably to the genius of his master Alla, the entire and permanent conquest of those countries was not accomplished till about three centuries afterwards.

In the year 1316, Alla died. An illness under which he laboured, was increased by a general insurrection, at the head of which was Cafoor. He not only directed his ambition to the usual objects, wealth and conquest, but, in the early part of his life, he had formed the plans of founding a new religion, and of leaving a viceroy in India, in order to rival Alexander the Great, after whom he called himself Secunder Sani, Alexander the Second. As he had raised himself to the throne by the murder of his uncle Feroze, he was constantly the prey of suspicion. In order to guard against conspiracies and rebellion more effectually, he levied an immense army, whose services he endeavoured to secure by gratuitous advances of pay; he confiscated the property of several men of rank and influence in the empire; he published an edict, forbidding all private meetings among his grandees, and prohibiting the use of wine, and all intoxicating liquors; he strictly forbade the nobles to marry without license from him; he ex- acted from his Mahomedan as well as his Hindoo sub- jects, half the yearly produce of their lands; and ho
the empire: he died in 1388. The grandson of Ferzo, who seems to have succeeded to the throne, reigned only but five months; rebellion and civil war raged, and prepared the kingdom for foreign conquest. The nobles having put him to death, placed his cousin on the throne; but he also was unfortunate; for his uncle, Mahomed, returning from the exile into which he had been driven, recovered the dominions of his father; civil war still raged, and the historian relates an unusual circumstance which arose out of this civil war,—two emperors in arms against each other, residing in the same capital. In the mean time, an independent kingdom was rising up in the Deccan, which was founded by Houssan, who had been a general under Mahomed III. before his time, Deogire had been the capital of this part of India, but Houssan fixed his residence at the ancient Koolbourga, which he named Ahssunabad.

In the year 1597, intelligence was received at Delhi that Timur Bec was approaching; this famous conqueror, after having overrun Persia, Turkestan, and part of Russia, turned his ambitious views towards Hindostan. During this year, he had sent his grandson, Peer Mahomed, to reduce the Punjab and Multan; and in the month of October, he crossed the Indus himself. When he first proposed to his princes the invasion of Hindostan, he was answered by a murmur of discontent and despair. "The rivers, and the mountains, and the deserts, and the soldiers clad in armour, and the elephants, destroyers of men." These things his princes thought it was impossible to overcome; but when they perceived he was determined on the invasion, they gave way to his superior judgment, or were terrified into submission by his dreadful character. He had been informed by his spies, of the weakness and anarchy of Hindostan; the souls of the provinces had erected the standard of rebellion; and the monarch was despised and disobeyed, even in his capital. The Mogul army moved in three divisions; between the Shy-lum and the Indus they crossed one of the ridges of mountains, styled by the Arabian geographers, the stony girdles of the earth. The mountaineers, after a brave resistance, were reduced or exterminated; but great numbers of men and horses perished in the deep snow; the emperor himself was obliged to let down one of the precipices on a portable scaffold, the ropes to which were 150 cubits in length, and before he could reach the bottom, this dangerous operation was five times repeated. He crossed the Indus at the passage of Attok; from this place to Delhi, the direct and most frequented road measured only 600 miles; but Timur deviated to the south-east, for the purpose of joining his grandson, who had by this time succeeded in the conquest of the Punjab and Multan. Being in want of provisions, he gave up the large and populous town of Tulumbini to the plunder of his soldiers; and when its inhabitants murmured at this conduct, he directed them to be massacred. After crossing the Hyphasis, he entered the desert, reduced the fortress of Batner, and advanced with little or no resistance to the city of Delhi.

In the mean time, the contending parties in the capital united for their common defence. The siege, more especially of the castle, might have been a work of time, but Timur, by the appearance of weakness and indecision, tempted his adversaries to descend into the plain, with 10,000 cuirassiers, 40,000 foot guards, and 120 elephants, whose tusks are said to have been armed with sharp and poisoned daggers. Timur,
though imputious, was not destitute of prudence. In order to protect his troops against these numerous and formidable opponents, he made use of some extraordinary precautions of fire, and a ditch of iron spikes, and a rampart of bucklers; but the troops of the Emperor of Delhi were totally unable to cope with the Moguls; for, as soon as the elephants were routed, they fled in every direction. The emperor and his prime minister seeing no possibility after this defeat of defending their capital, escaped under cover of the night, and fled towards Gujarat, whether they were pursued by a strong detachment, which Timur sent after them. This detachment came up with them; an engagement took place, during which the emperor effected his further retreat, with the loss of two infants sons, and a considerable number of his retinue.

Timur, in the mean time, made his triumphant entry into the capital of Hindostan, where he received the submission of all the principal nobles. To them he promised pardon and protection, on condition that they would pay him immense sums of money. Orders were accordingly given to the magistrates to levy the contribution by a scale proportioned to the wealth and rank of the inhabitants. The Tartar officers who were employed to receive it, not satisfied with the regulated sums, violently broke into the houses; this occasioned resistance, in the course of which some of Timur's troops were put to death. Timur immediately issued orders for a general massacre. Delhi was sacked; its palaces and temples burned, and its streets filled with blood. Timur remained in Delhi only fifteen days, and appears then to have designed to return to the seat of his empire, when having heard of a fortress on the Doob which had resisted the arms of a former Mogul invader, he changed his purpose, marched into that district, and reduced the fortress. While here, information was given him respecting the famous cavern of Coupele, and the religious ceremonies which were practiced at it by the Hindus, in consequence of its resembling a cow's mouth, and the Ganges flowing through it. This information excited the persecuting spirit of this barbarian, and he determined to purify his soldiers in the blood of the idolatrous Hindus. In this he succeeded. His return was along the skirts of the northern hills, by Mount Sewalik; in his route, he committed his massacres, though not without opposition, until he arrived on the borders of Cashmer.

His return was occasioned by disturbances in some of the provinces of his empire, stirred up by the famous Lajazet. On the banks of the Ganges he received intelligence regarding them, and in little more than five months he had crossed and recrossed the Indus. He may be said, however, rather to have overrun than to have reduced and conquered; for he did not disturb the order of succession in Hindostan, reserving to himself the possession of the Punjab only. During his life, which terminated in the year 1405, he was prayéd for in the mosques of Hindostan, and the coin was struck in his name; but this might be more the effect of policy than the act of Timur. For, soon after he left Hindostan, his authority virtually ceased in Delhi—that capital became the prey of the most dreadful and cruel descensions; and while in this state, it was seized upon by a petty usurper. He, however, was soon driven from his throne, and Mahomed, who reigned at the period of the invasion of Timur, was replaced on it. But his authority was very confined; for the soubans of the provinces taking advantage of the Mogul invasion, and its immediate consequences, revolted from the supreme government of Delhi.

In 1413, Mahomed died, and with him ended the Pagan dynasty. Several sovereigns, supported by different parts of the army, set themselves up in different provinces. At length the throne was occupied by Chiter, who styled himself a Seid, or descendant of the holy line of the prophet Mahomed. In order not to rouse the hostility of the Mogul princes, he did not assume the imperial titles, but represented himself as holding his authority under them. This, however, did not preserve his territories from invasion; for, during the space of nearly thirty years, the Moguls retained possession of the western states of Hindostan, from which they made frequent incursions into those which lay nearer Delhi. After a turbulent reign of seven years, Chiter died. He was succeeded by his son Mahbaric Shah, of whom Ferishta says, "he reigned 13 years; he was esteemed a man of parts, just and benevolent; and though no great warrior, had he lived in a virtuous age, there is no doubt but he possessed talents which might have rendered him worthy of a throne." During the next 27 years, the throne was filled by his nephew and his son Alla.

The feeble and inauspicious dynasty of the Seids terminated, A.D. 1450, by the abdication of Alla, and A.D. 1450, the subsequent elevation of Belloli, an Afghan of the commercial tribe of Loudi, by whom an inland trade was carried on between Persia and Hindostan. Belloli is represented as a humane and generous prince; but being destitute of talents and vigour, he was totally unqualified to preserve the empire under the circumstances of dissenion and weakness in which it was placed. In 1458, it was dismembered. All Hindostan fell into separate governments, and the authority dismembred of the emperor did not extend beyond the province of Bered, Delhi and the contiguous districts. The whole of Ben-gal and Bahar was under the dominion of a Mahommedan usurper, who had taken the title of king. A potentate, styled King of the East, whose residence was at Joupour, in the province of Allahabad, was the most formidable of these petty sovereigns. The provinces of the Decam, north of the Krishna, had long thrown off their allegiance, and were now formed into five Mahomedan states, equally independent of each other, and of the imperial government. Yet though the monarchs of Delhi had thus lost their influence and power, they still retained their diadem; and Secunder, the son of Belloli (who reigned 38 years) an enterprising prince, would probably have regained some part of its dignity, had not a premature death put an end to his projects. He died at Agra in 1509, to which city he had transferred the seat of government.

He was succeeded by his son Ibrahim, a man of a very different character. He rendered himself ridiculous by his vanity, and detested by his cruelty. The horrors of civil war and assassination were spread over the country. At length the nobles, who were apprehensive that they were not of themselves equal to the task of getting rid of their tyrant, solicited the assistance of Sultan Baber, the Mogul prince of the house of Timur Bec. This sovereign reigned over a kingdom composed of most of the provinces situated between the Indus and Samarcand. Having been stript of the northern parts of his dominions by the Uabecs, he determined to try his fortune in Hindostan, and accordingly most readily accepted the invitation of the

nobility of Agra. His residence was at Cabul, whence he undertook his first expedition across the Indus, in the year 1517. But it was not till six years afterwards that he took possession of Lahore, and the next year he marched to Delhi. Before he reached that city, Ibrahim met him with a large army, and a fierce battle ensued on the plain of Panampil. In this battle, 16,000 Patans, with Ibrahim himself, were killed. Thus an end was put to the dynasty of Lodi. Baber, in consequence of this victory, proceeded first to Delhi, and afterwards to Agra; both these cities opened their gates to him, and he was proclaimed Emperor of Hindostan, in the year 1525. It is said that he crossed the Indus the last time with only 10,000 chosen horse, the enemy’s generals, by their revolts, furnishing him with the rest of his army. The provinces which he gained were those of Multan, Lahore, Delhi, Agra, Ajmeer, and Oude: for, as we have already remarked, the empire of Delhi was no longer the same that flourished under Balin. The province of Bengal was completely separated. The rich countries of the Decan were the seat of another empire. Guzerat did not even nominally acknowledge the sovereigns of Delhi, and the mountain tribes of Patan were independent, or at least troublesome and restless subjects.

The reign of Baber, even in those districts which he gained, was by no means free from anxiety and disasters. He was frequently harassed by insurrections, and at one period his fortune seemed so desperate, that his nobles advised him to return to Cabul. To this, however, he would by no means agree; and by his moderation and firmness, united to a considerable degree of talents and activity of mind, he overcame all obstacles, and placed his kingdom in a state of comparative tranquillity. He died in the year 1530. His character may be thoroughly understood, both from the account given of him by Ferishta, and by the memoirs of his life, written by himself; and the historian does not appear to have drawn it in too flattering colours in the following terms: “He so often rewarded ingratitude and treason, that he seemed to make it a principle and rule of his life to return good for evil; he thus disarmed vice, and made the wicked the worshippers of his virtue.” He was the first of the Moguls, in whose tenets and doctrines he was perfectly versed; but he yielded more to the evidence of reason than to the marvellous legends of supersitious antiquity. He was not, however, forgetful of that rational worship which is due to the Great Creator, nor a desirer of those laws and ceremonies which are founded on sound policy. He excelled in poetry and music, and he wrote his own commentaries in the Mogul language with such elegance and propriety, that they are universally admired.” The historian adds, that he was fond of pleasure, though moderate in its enjoyment; and that he was equally celebrated for his clemency, courage, and justice. As an instance of the latter, he relates, that a caravan from China having been buried in the snow in crossing the mountains, he caused the merchandise to be collected, and sent notice to China of what had happened, in order that the owners might claim their property; and he restored it to them, refusing to be reimbursed even the expenses he had incurred.

His eldest son, Houmaion, who had been the companion of his victories, and the partaker of his fame, succeeded him; but the short reign of Baber had not allowed time enough to compose the distractions that prevailed, or to exterminate the seeds of rebellion. After having subjugated the valuable provinces of Guzerat and Malwa on the west, and those of Bengal and Bahar on the east, the viceroy of which, as it has been stated, had declared themselves independent of the supreme government, he found himself compelled to abstain from future conquest, and to turn his whole attention to his domestic concerns. The Patans were encouraged to disturb the tranquillity of his kingdom by his own brothers, to whom he had generously offered to give up one half of the empire. This they refused; and after 12 years of civil war, and encountering every species of distress and difficulty, Houmaion was obliged to flee for refuge and protection, first towards the Indus, and the Rajput princes of Ajmeeer, and afterwards to the court of Fath Tumash, King of Persia.

In the mean time Shere, an Afghan chief, ascended the throne of Delhi; and one of the brothers of the exiled emperor possessed the provinces to the west of the Indus. Shere was a man of extraordinary talents, and a brave and skilful warrior. He built caravansaries for every spot at every stage, from Bengal to the Indus, a distance of 3000 miles; and planted fruit trees along the road, for the accommodation of the passengers. He was the first who established horse-ports in India, for the purposes of government and commerce. In his reign such was the vigilance of the police, that travelers rested and slept with their goods in the highways with perfect security. These are proofs of the good qualities which he possessed, and exercised for the improvement and benefit of his country; but, on the other hand, he was cruel, vindictive, and treacherous. He was killed by the bursting of a shell at the siege of Chei- tore, after a reign of five years, A.D. 1515.

His eldest son Adil succeeded him; but this prince was so totally unfit, and so little willing to govern, that, before he was crowned, he resigned his title to Selim his brother. So very unsettled was the state of Hindostan at this period, that no fewer than five sovereigns appeared on its throne in the course of nine years. In effect there could not exist in the minds of the people any idea of regular and fixed government; for there had been scarcely twelve years in succession during two centuries, that did not furnish some example of successful rebellion. This induced a strong party in Hindostan to invite Houmaion back. Secunder, the nephew of Shere, who had assumed the imperial title, and resigned at Ajmeeer, made great preparations to resist the invasion; but Houmaion, having been assisted by the king of Persia, and by the troops of several Tartar and Mogul tribes, was too powerful for him. The battle of Serhind, which was fought in the year 1554, was decisive of the fate of Delhi, and destroyed for ever the Patan power. Houmaion, however, did not long enjoy his crown; for, in consequence of an accident, he died the year subsequent to his victory. He was celebrated for the mildness and benevolence of his disposition, and not less for his great personal bravery.

He was succeeded by his son Acher, who had been born when he was an exile among the princes of Ajmeeer. Acher was about 14 years of age when his father died. The reign of this sovereign is the most prosperous and brilliant in the history of the Mahomedan empire of India. Even at the commencement of his reign, he conducted himself with a prudence and dignity rarely found united in so young a person, especially in the difficult circumstances in which he was placed. He had been left by his father under the special guidance of Byram Khan, who was appointed minister during his minority, and who was a man of great abilities, but of a boundless ambition and an impetuous tem-

His excellent character.
Aber had the consummate address to render his minister's talents solely subservient to the necessities and advantage of the state; while at the same time, by asserting his own authority on every proper occasion, he maintained the passions of Byram, and placed limits to his ambition. The unsettled state in which the empire had been left, required all the talents and resolution, and occasionally all the hardiness of the minister, and all the bravery and gentleness of the prince, to reduce to any kind of order the discordant materials of which it was composed. The first act of Aber gave pleasing and satisfactory preface of the principles on which he intended to regulate his conduct. He issued orders prohibiting the execution of the present money, on the accession of the new sovereign, from the farmers, forbidding the pressing of labouring men for the wars, and permitting all goods to pass from one part of his dominions to another toll free.

The first years of Aber's reign were employed in the reduction of the revolted provinces, from Ajmeer to Bengal. In this enterprise Byram was a principal actor. As soon as these provinces were restored to the empire, Aber endeavoured to preserve them, by a proper choice of governors; by wise regulations; by an unlimited toleration in religious matters; and by a proper attention to the habits and wishes of the people. The Hindoos still formed the great mass of his subjects; and the emperor had learnt from past events, that the passive religion and temper of those people would, if left to themselves, never disturb the established government.

Aber, soon after the reduction of these provinces, had a difficulty of a far different kind to struggle with; for his minister Byram, being offended at his master's endeavours to emancipate himself from his guidance, took up arms against him, under the pretence of a pilgrimage to Mecca. He was, however, soon overthrown; and gratitude for the substantial benefits he had received from him, as well as the natural kindness of Aber's nature, prompted him to grant a full pardon to the rebel. The sovereign invited him with kindness to return to his service; and when Byram threw himself at the foot of the throne, he took him by the hand, raised him up, and throwing a robe of state over him, placed him in his former rank at the head of the nobles. "If," said Aber, "the lord Byram loves a military life, he shall have the government of Calpe and Chhindore; if he prefers remaining at court, he shall be loaded with favours; and should religion prompt him to go on a pilgrimage to Mecca, he shall be escorted in a manner suitable to his dignity." Byram preferred the pilgrimage, and Aber gave him a suitable retinue, and 50,000 rupees to support him. On his journey to Mecca, he was unfortunately murdered, with his guard, by some of the Afghans of the tribe of Lodi.

In the year 1585, he resolved to attack the Decan; and soon afterwards carried the war into Berar, while another army was reducing Cashmere in another corner of the empire. The Decan appears at this time to have been divided into the states of Khandelish, Dowlatabad, Goelconda, and Bijapoor. Berar and the Carnatic, each of which included several distinct governments, do not seem at this period to have been included in the Decan. Most, if not all the four states just enumerated, were governed by Mahomedan princes. In his attempts against the Decan, Aber was not completely successful; for at the period of his death in the year

It and the contiguous provinces, than the occupying the western part of Berar. Khandelish, Tellugana, a division of Goelconda, and the northern part of Dowlatabad. The capital of this last province was taken in the year 1601, Thara long, and bloody sieges, and an unsuccessful attempt to relieve it, by the confederate princes of the Decan.

In these wars Aber himself was not engaged. They were carried on by his sons, and the Patan and Hindoos chiefs on the frontiers. In the mean time, the emperor himself, with his minister the learned Abul Fazel, was employed in regulating the internal management and economy of the kingdom. Inquiries were set on foot, by means of which the revenue, population, produce, religion, arts, and commerce of each individual district were ascertained, as well as its extent and relative position. Most of these important and useful particulars were by Abul Fazel collected into a book, called the Ayeen Aecbar, or Institutes of Aber. Hindostan proper was divided into eleven soubahs, some of which were in extent equal to large European kingdoms. The soubahs were again divided into circars, and these subdivided into pargunnas. The names of the original soubahs, as well as of those which were added, have already been given; and the leading particulars relative to the extent, &c. of each soubah, will be noticed when we treat of the statistics of India. At present, we shall only offer a few remarks taken from Major Lennell, on the boundaries of those soubahs that bordered on the Decan, in order to have a more precise and accurate idea of the conquests of Aber.

"Guzerat extended southward to Damaun, where it touched on the district of Bagiana, a division of Amednagur.

Malwah extended to the south of the Nerbudda river; and an angle of it touched on Bagiana and Khandelish, on the south-west and south, and on Berar on the east. The Nerbudda formed the rest of the southern boundary of Malwah, and also of Allahabad. The government of Bengal extended to Cuttack, and along the river Mahanuddy; but the soubah of Orissa appears not to have been formed at that time.

Of the newly erected soubahs in the Decan, Khandelish, the smallest of them, occupied the space between Malwah on the north, Berar on the east, and Amednagur on the west and south.

Berar had Allahabad and Malwah on the north; Khandelish and Amednagur on the west; Tellugana and Goelconda on the south; and Orissa on the east, as already stated, only the western parts of Berar were reduced by Aber.

Amednagur, the southmost of Aber's soubahs, had Khandelish and Malwah on the north; the Gant or Balsagaut mountains on the west; Visiapour and Tellugana on the south; and Berar on the east. The limits of this soubah are not defined in the Ayeen Aecbar; and as Aber had wars in the Decan during almost his whole reign, it may be supposed that its limits were perpetually fluctuating.

Tellugana, which in the Ayeen Aecbar is called a circar of Berar, was possessed only in part by Aber. Tellugana, of which Warangole was the capital, comprehended the tract lying between the Krishna and Godavrey rivers, and east of Visiapour, (answering to the modern province of Goelconda,) and was probably in more early times an extensive kingdom."

After Aber had ascertained, by the enquiries he instituted, the condition and the wants of the different provinces of his vast empire, he applied himself most
industriously and wisely to their improvement. Schools were established, in which both the Indian and Arabic languages and sciences were taught. Translations of works both of instruction and taste were made at his express desire, and under the direction and superintendence of Abul Fazul. Under his mild and equita-
ble government, agriculture flourished, commerce re-
vived, the arts prospered, and his subjects enjoyed the fruits of their increased industry, free from those apprehensions of insecurity to which they had been so long exposed. Acker participated in the prosperity of his people. His regular annual revenue amounted to nearly £30,000,000 sterling; and from sources less re-
gular and permanent, he frequently derived in the course of the year about twenty millions more. His armies were not less remarkable for their numerical strength, than their excellent equipment and discipline. They consisted of about 500,000 horse, and an equal number of foot. They were composed principally of detached tribes under independent chiefs; and, from this circumstance, it required all the vigilance and vigour to prevent rebellions and insurrections from being much more frequent and dangerous than they actually were. Acker died after a reign of 51 years, in the year A.D. 1605. Prince Daniyal, his eldest son, died just before him.

Selim succeeds.

Immediately on his decease, a powerful party of the nobility intrigued for the purpose of placing Khusru, the son of Selim, Acker's only surviving son, on the throne; but their designs were frustrated, and Selim succeeded. The new monarch assumed the appellation of Jehanghire, or conqueror of the world. Scarcely was he seated on the throne, when his nephew Khusru engaged in open rebellion; to this step he seems to have been led rather by the advice and intrigues of the nobility, than by his own wishes or judgment. The rebellion, however, was soon quelled, and Khusru thrown into prison. As soon as Jehanghire had restored internal tranquillity to his kingdom, he turned his thoughts to the conquest of the Deccan. He seems, however, from some cause, not very apparent, not to have pursued this object with perseverance or zeal. War was also made on the Rajpoots, and the Rana, or chief prince, compelled to sue for peace, on terms most favourable to the emperor.

Jehanghire was a man of talents, and would have proved himself such by his conduct, had not his coun-
cils been rendered vacillating and weak, and his go-

vernement been constrained, by the influence of his mistress Noor Jean. She was the daughter of Ainaas, a Tartar, and was born in the wilderness, to which the poverty of her father had obliged him to flee. Ainaas afterwards came to the court of Jehanghire, and being a man of considerable abilities, and of probity, he was soon noticed and patronized; his daughter was educa-
ted with the greatest attention and care; and she soon became one of the most accomplished women in Asia. As she was also greatly distinguished for her beauty and her wit, she was not long in attracting the particular notice, and exciting the warm affection, of the young prince Selim. He requested his father Acker to de-
mend her in marriage for him; but as she was betrothed to Shere Afkhu, one of the most accomplished and bravest nobles in India, Acker refused to interfere. Selim therefore was obliged to wait till he ascended the throne, when, his passion still being as ardent as be-
fore, he resolved, by whatever means, to gratify it. Noor Jean was by this time married; but this circum-
stance possessed no weight in the mind of the new

sire, who caused her husband to be assassinated, and the widow to be conducted to the royal Zenana. She soon proved that she did not bear implacable resentment against the murderer of her husband, and that her ambition was more powerful in her breast than affection. She became the wife of Jehanghire, and shortly afterwards her influence over him was almost without limits. Her father and brothers were raised to the first offices in the empire, and her relations, to the most remote degree, came from Tartary to the Mogul court, where she heaped upon them wealth, rank, and power.

In one respect, however, her influence, and the situa-
tion to which he was raised, was beneficial not only to the emperor, but also to the kingdom at large. Her father was appointed prime minister; and as his talents were not weakened nor abused by his elevation, and his probity remained unimpaired, he did great service to the state. Under the name of Acemad ul Dowlah, he exercised the office of prime minister in such a man-
ner till his death, that his name is to this day revered by the people of Hindostan. The principles upon which he administered the government were similar to those upon which Acker had conducted himself; he regarded the industry of the people, not only as the only source of wealth and prosperity, but also as the surest defence against foreign foes, and the best preservative of internal quiet. Forests were cut down, and towns and villages were built; manufactures flourished under his auspices; but it was to the improvement of agriculture that he specially directed his attention and his measures. Those provinces, which during war had been desolated, were repeopled and cultivated. Religious persecution was unknown; the Hindoo and the Mahomedan were equally the objects of his care, and placed equally un-
der the protection of the laws. It was in this reign that Sir Thomas Roe was sent as the first English am-
bassador to the Emperor of Hindostan. He presented a

court to Jehanghire from James I.; and, in spite of the opposition of the Prince Royal, obtained the object of his mission, which was leave to establish a factory at Surat. In the second division of this article, the European establishments will be particularly consid-
ered; we shall therefore only remark in this place, that the Portuguese had by this time acquired considerable settlements in Bengal and Guzerat; but only those at Guzerat, where they also possessed some extent of terri-

tory, attracted the notice of the court; and it is cu-

rious to observe in what terms the author of the Ayeen Achari mentions them. Speaking of the lands of Gu-
zerat, he says, "By the neglect of the king's governors, several of these districts are in the hands of Europeans." Ferishta also, mentioning the site of an ancient Hindoo temple near Diis, says, that it was situated in the dis-

tracts that were subject to the "idolaters of Europe." The rebellions of his son, Shah Jahan, embittered the latter part of his reign; and these rebellions were sometimes fostered and strengthened by the nobles, whose martial habits rendered a life of peace irksome to them, and sometimes excited by the intrigues of the empress.

Jehanghire died in 1628; at the time of his death he was on a journey to Cashmere, in the hot and beau-
tiful valleys of which he was accustomed to reside du-
ring the sultry months of summer. "This monarch had the character of being a Deist, because he protect-
ed the followers of Brahma and Zoroaster, and even toler-
ated Christians as well as Mahomedans; he was most rigorous in administering justice, punishing even those he loved, without regard to greatness of situation or
The Mogul dominions were considerably enlarged during the reign of Shah Jahan; the conquest of the Deccan was pursued with great vigour, and the plunder and devastations perpetrated there, occasioned most of its princes to make submission, and acknowledge the emperor as their sovereign. The whole of Bengal was entirely subdued; and the states of Tibet and Assam were kept in awe; Candahar was recovered from the Persians; Cashmere was governed by a viceroy from Delhi; and Guzerat was reduced to obedience. Golconda was in part actually taken possession of; but Bejapoor and the Carnatic, together with the region of the Gouts, remained in the power of their ancient possessors. In the wars, during which these conquests were achieved, Shah Jahan was principally indebted for his success to his general Mohabat, his son Khan Ziman, and on their death, to the military talents of his own sons. There were four of them, Dara, Sujah, Aurengzebe, and Morad. The characters and talents of all these were distinctly marked, and though in some respects they resembled one another, yet in many material points, there were great and striking differences. Dara was undoubtedly most richly gifted, by nature of all the sons, both in the qualities of his mind, and in the virtues of his heart. Like all the princes of the house of Baber, he was well versed in the learning of Persia and Arabia; and he caused himself to be instructed in the ancient learning of Hindostan by some Hindoo Pandits, whom he liberally paid for that purpose; he was even anxious to acquire some insight into the literature and the customs of Europe; and in order to gratify his desire in this respect, he paid great attention to, protected, and encouraged the Jesuits, who had a college at Agra. In his temper he was frank far beyond what the manners and habits of the cast required or sanction; and his generosity was unbounded, and not always under the guidance of a discriminating prudence. In his person he was remarkably handsome; and his address was elegant and insinuating. Possessed of these qualifications, he was deservedly a favourite with almost all classes and descriptions of his father's subjects. Sujah, the second son, was distinguished for his prudence, which directed or restrained the openness of his temper, and the generosity of his disposition, much more than Dara was inclined or could be induced to do; but his prudence, though a guard against the excess of these qualities, was but a feeble barrier, when the attainment of pleasure was Sujah's object; in this respect he was weak and unstrained. Both these sons were distinguished, and nearly in an equal degree, for their talents and success as warriors; but the third son, Aurengzebe, was superior to either of his brothers, in the politics, the skill, and the bravery, which a state of warfare demands. As he was inferior to his brothers in the advantages of person and address, he endeavoured, and but too successfully, to compensate for these deficiencies, by dissimulation and intrigue. Wreapt up within himself, though apparently open and artless, he threw his adversaries off their guard, and succeeded at one and the same time, in concealing his own sentiments and plans, and in developing those of others; when it was necessary to gain over his opponents, or to make use of them as instruments in his own hands, he displayed wonderful powers of address, and exquisite knowledge of the weak parts of the human character. It is evident that such a disposition and habits as Aurengzebe possessed, aided by no mean talents, and the happy and not common art of having these talents always at command exactly where they were wanted, were capable of producing much good, or much evil, according as they were directed. Unfortunately, ambition, of no low standard, was the ruling passion of his heart; and this ambition, which aimed at as high power as lay within his reach, he was resolved to gratify, without the smallest compunction of conscience regarding the measures, which it might call upon him to execute. But he well knew, that as he was not the eldest son, it would be indispensably necessary to keep his ambition concealed from every eye; he therefore affected the habits of a Faqir, and used religion as a mask to cover his designs. The distinguishing features in the disposition of the fourth son, were violence and impatience; but they were not the violence and impatience of a bad heart, or of an unfeeling temper; they were rather constitutional than the result of thoughtlessness or vice, and they were accompanied, as is often
the case, where they are of this venial description; by a great share of openness and sincerity; in courage he surpassed all his brothers. Of the daughters of Shah Jehan, two only require particular notice; the eldest, Jehanara, resembled Dara, in almost every respect; and these two were, of all the emperor’s children, the most remarkable for filial piety, and for mutual affection. Roshenara resembled her brother Aurungzebe in disposition; and this similarity induced her always to support his interest and plans as far as lay in her power.

Shah Jehan, who had a clear insight into the characters of his sons, was very apprehensive that on his death disputes might arise among them: partial to Dara, not more, perhaps, because he was the eldest, than on account of his excellent qualities, he made him the associate of his throne, and commanded respect to be paid to the signet of Dara, equal to that which was paid to his own. In order, however, that this might not rouse the jealousy of his brothers, he at the same time made Sujah governor of Bengal, Aurungzebe governor of the southern provinces, and Morad governor of Guzerat. But this very measure, in one respect, defeated the object which the emperor had in contemplation; for Dara being necessarily near his father, while his brothers were at a distance, they were disposed to regard their appointments as given them not so much to place them on a footing with Dara, as to remove them from the seat of government, and consequently to deprive them of the chance of contesting the throne with him, in the event of their father’s death.

As long as Shah Jehan continued in health and vigour, the authority of Dara was not questioned by his brothers; but in the year A.D. 1657, the emperor having been seized with a stroke of the palsy, was obliged to give up the entire government to his eldest son. As soon as the other brothers heard of their father’s illness, they immediately anticipated a fatal issue, and apprehending the destruction of their power as soon as Dara should ascend the throne, they each, without communicating with the other two, resolved to march with the utmost expedition to Delhi. The intelligence of the approach of Sujah first reached the seat of government; and as Dara did not deem it prudent to leave Delhi himself, he dispatched his son to oppose Sujah. The hostile armies met near Benares; a battle was fought, which terminated in the defeat of the invader, who retreated his steps into Bengal for the purpose of raising new forces. But the danger with which Dara was surrounded was very little lessened by this defeat: Sujah, from the position of his government, had been obliged to commence hostilities without aid from his brothers; but they had it in their power to unite their armies; and this they actually did: Aurungzebe, on his march from the Decan, being joined at Brahmputra by Morad, with his troops from Guzerat. While Aurungzebe possessed the government of the Decan, his ambition had not been asleep, nor had it been unaided by those talents and habits, which were so well calculated to attain its gratification in the most unsuspicous and certain manner. Meer Jumla, a man of low origin, but of an enterprising turn, had raised himself to great power, and acquired immense wealth at the court of the princes of Golconda; but, in consequence of some affront which he received, he fled to Aurungzebe, bringing along with him all his treasures. To make this man his friend, Aurungzebe was incited, not less by the consideration of his riches and forces, than of his abilities; accordingly he received him in the most kind and flattering manner, and soon gained such an ascendancy over him, that he found no difficulty in persuading him to join in the attempt to deprive Dara of the throne of Delhi.

As the united forces of Aurungzebe, Morad, and Meer Jumla were very numerous, Dara resolved to oppose their progress by every means in his power; accordingly an army, under a general whom he could depend upon, was stationed on the banks of the Nerbudda, to contest the passage of that river; but the attempt was in vain; the army of Dara was defeated, and Dara then deemed it necessary to advance against his enemies. The brothers met near Agra; a battle was fought; victory seemed doubtful for a considerable time, and turned in favour of the invaders only in consequence of an apparently trifling circumstance. Dara was obliged to dismount from his elephant from different accidents; and the soldiers no longer seeing him at his station, were panic struck and fled. Aurungzebe and Morad thus gained a decided victory.

The next objects which Aurungzebe had in view was the capture of his father and his brother Jahan, to accomplish the latter, he marched within loss of time after the battle to Agra; and that city presenting the prospect of a resistance, which he had not leisure or means to overcome, he had recourse to stratagem, and thus gained possession of it. His father consequently fell into his power, and he imprisoned him, his daughter Jehanara, and the infant daughter of Dara, in the fortress. In the mean time Dara had fled to Delhi, and against that city Aurungzebe now directed his march. Hitherto he had succeeded in persuading his brother Morad, that it was for his sake alone he was anxious to deprive their father and brother of the throne; and that the only reward he sought for himself was a hermitage, in which he might spend the remainder of his life, at a distance from the cares and v Vanities of the world. But his real projects now became apparent, and Morad regarded him with suspicion and alarm. As Morad was the favourite of the troops, and besides had a great number of personal friends, Aurungzebe resolved to remove him; and this he did, not in his accustomed dark; and crafty manner, but openly; for having invited him to a sumptuous entertainment, he caused him to be seized and murdered. It does not appear that this most violent measure created any disturbance, for after its perpetration Aurungzebe immediately marched to Delhi. He did not, however, assume the sovereignty, without the mockery of appearing to have it forced upon him, by the urgent representations and entreaties of his friends: as soon as he became emperor, he took the appellation of Alumghire, or conqueror of the world. As soon as Sujah heard of the death of one of his brothers, the defeat of the other, and the successful enterprise of Aurungzebe, he collected a large army, and commenced his march towards Delhi; as he was now the only obstacle which stood between Aurungzebe and the entire and secure possession of the throne, the latter immediately made preparations to oppose him; and as soon as he had completed such measures as were necessary to keep Delhi quiet during his absence, he left that capital with a powerful army. The two brothers met at Kedgara, about 30 miles from Allahabad; the battle which ensued was obstinate and bloody, but it terminated in the defeat of Sujah. Yet, notwithstanding this defeat, Sujah was still a formidable opponent; and his farther resistance was rendered peculiarly harassing to Aurungzebe, as well as dangerous, by
the following circumstance. Mahomed, the son of the emperor, was attached to one of the daughters of Sujah; he was placed under the care of Meer Jumla, to whom was entrusted the pursuit of Sujah; as soon as the two armies approached each other, Mahomed took an opportunity to leave the camp of Meer Jumla, and to join his uncle. This circumstance rendered it the more necessary to bring Sujah to an engagement as speedily as possible; accordingly Meer Jumla attacked him at Tanda, a town in the province of Bengal, adjacent to the ruins of the ancient city of Gour, and again defeated him. Aurengzebe, as soon as he heard of the defection of his son, wrote him a letter, the object of which was, in a most amiable manner, to rouse his suspicions of his uncle and father-in-law. This letter had the desired effect; and Sujah perceiving that Mahomed was no longer happy with him, sent him off, along with his wife, and jewels to a large amount. With respect to himself, having no longer any chance of opposing Aurengzebe, or even of standing his ground in the plain country, he fled, after the battle of Tanda, to the mountains of Tipperah. Among these, and in the adjacent countries, he wandered almost forgotten for many years, till at length he was destroyed, together with the greater part of his family, by the Ilaaj or Arracan. Mahomed, as soon as he returned to his father, was thrown into prison, where he remained till his death. With respect to Dara, he was, if possible, still more unfortunate than either of his brothers: After wandering about in the deserts, he seems to have taken up his residence at the court of Jihon, a petty prince in the province of Bichar, west of the Indus. At first he was hospitably received; but afterwards, probably in consequence of the interference of Aurengzebe, he was seized and sent to Delhi. There he was obliged to mount an elephant, and after being exposed to the inhabitants as a captive, he was murdered by the orders of his brother.

Aurengzebe was now seated, without a rival, on the throne of his father; the empire which he governed was extensive and powerful; at the death of Shah Jehan, it stretched from Cabul to the Nerbudda; westward of this river to the Indus, and to the eastward, it comprehended Bengal and Orissa. To the south of the Nerbudda, the Moguls had reduced the countries dependent on Brampore, Aurungabad, Ahmednagar, and Boder; and these had been connected into one government. This territory was bounded on the east by Berrar, westward by the hills towards Concan, and by the dominions of Golconda and Bejasore to the south.

As Aurengzebe had governed in the Decan during his father's lifetime, it is not surprising that his ambition directed its views of conquest principally to that part of India; but it was not till the year 1673 that he could in person, and with all his force, invade this district. In the mean time, a power was rising up in the Decan to resist the and, after various vicissitudes, to retaliate on his successors the injuries of his sword. This was the state of the Mahrattas.

In the ancient fables of the Himloos, the term Maharshee is applied to a geographical division of the Decan, comprehending principally its north-west quarter. It is supposed, that the original country of the Mahrattas included Khandesh, Bogolee, and part of Berar, extending, in a north-west direction, as far as Cutch and the Nerbudda. They possessed the narrow but strong country that borders on the Concan, and stretches parallel with the sea from near Surat to Canara. The original Mahratta state comprehended a country of great natural strength, interspersed with mountains, defiles, and fortresses, and admirably calculated for defensive warfare. It does not appear, however, that the original Mahrattas were of the military cast; for the names of their principal tribes signified farmer, shepherd, and cowherd. It appears extraordinary, that a nation so numerous as the Mahrattas, should have been almost unnoticed in Indian history till the reign of Aurengzebe. Nasirah, one of their princes, is indeed mentioned in A. D. 1591, by Ferishta; but it is probable that, prior to the time of Aurengzebe, their country, like the other parts of the Decan, was divided into little principalities, many of which depended upon the neighbouring Mahrmanedan chieftains, but were never completely brought under subjection.

In the middle of the 17th century, Sevajee suddenly arose; one of those men who, by a fortunate conjunction of rare talents and rare opportunities, raise nations from obscurity to the highest pitch of fame. His father had been minister to the king of Bejapore, and, having obtained possession of the wealth which he had collected, he raised a band of adventurers, and, by means of them he seized some strong fortresses in the mountains, near the sea coast. The security of these retreats, and the connections he had in the army of Bejapore, brought numerous bodies of troops to his service; while his abilities, and the desire of opposing a Mahrmanedan power, induced many of the raja to devote themselves to his cause. Under these circumstances, the king of Bejapore judged it necessary to send a strong army against him; but he first seduced, and afterwards murdered the general, and the army, deprived of their leader, broke up and dispersed. At this period Aurengzebe was in the Decan. He had reduced Golconda, but being obliged to return to Delhi, he was apprehensive that his conquest would be wrested from him by the king of Bejapore. He therefore endeavoured to gain the Mahratta chief as his ally; and, by congratulating him on his success, and putting him in possession of some forts adjoining to the kingdom of Bejapore, he succeeded in his scheme. Sevajee, enterprising and crafty, extended his dominions, till, by his plunder of Surat in the year 1664, he roused the suspicions and the anxieties of Aurengzebe. Besides the abundance of its commerce, this city was in high renown, as being the part through which the Moguls made their pilgrimage to Mecca, of which, in the archives of the empire, it was called the port. Aurengzebe felt the disgrace as well as the detriment of the insult. The whole army of the Decan, therefore, was ordered to invade the Mahratta territory; but Aurengzebe did not trust entirely to force: he also employed stratagem; and finding that Sevajee made a most obstinate resistance, he used all his arts to persuade him to make peace; and not only succeeded in this, but also prevailed upon him to come to Delhi. When he arrived at this city, he discovered that he had been deceived, and, burning with revenge, he contrived to escape, and place himself again at the head of his armies. Aurengzebe was now convinced that he had stirred up against himself a most powerful and formidable foe, who would not only defeat his attempts of conquest in the Decan, but most probably wrest from him the territories he had already acquired there. To reduce him by the sword was out of the question; he again attempted stratagem, but without success. Under these circumstances, Aurengzebe resolved to em-
plovw that knowledge of human nature which he so
emminently possessed; he knew that the Mahratta chief
was actuated by the most unbounded ambition, and
this passion he hoped to manage in such a manner as
to bring about his destruction.

In the year 1667, Aurengzebe appointed his son Ma-
homed Mauzun to the government of the Decan; and
the prince marched from Delhi with a numerous and
chosen army. As soon as he reached the Mahratta
country, he caused his troops to spread along the foot
of the hills, to the north and south of Jemniah-gur, in
such a careless manner, that the bands of Sevajee made
excursions through them, even to the gates of Beja-
pore. Aurengzebe, informed of this, wrote in a threat-
ening and displeased tone to his son; who, in his turn,
openly expressed displeasure at his father. At last
there seemed to be no doubt that the son had revolted.
In the mean time the Mahratta chief had, through his
spies, fully informed himself of the state of things
in the Mogul camp; he was not, therefore, surprised when
Mahomed applied to him for assistance against his
father; but Sevajee's suspicions were raised; he dreaded
a collusion between the father and son; and this he en-
devoured to ascertain by his spies, both in the camp
of Mahomed and at Delhi. He could, however, learn
or conjecture nothing; still he resolved to continue sus-
picious and guarded, till at last Mahomed was convin-
ced that it was impossible to overreach Sevajee. From
this plan, though unsuccessful, Aurengzebe however
reaped one advantage; for it had fixed such general distrust
on his son, as was likely to prevent him from
 gaining any support in any future intention of real re-
bellion.

About this period, the intrigues of the Persians had
incited several of the Patan tribes of Cabul to rebel
against Aurengzebe; but being deprived of the assist-
ance they expected by the death of the sphy of Persia,
they were left to the mercy of Aurengzebe, who punish-
ed them with vindictive severity. It was in the Decan,
however, that the emperor's schemes were carried on to
the greatest extent, and with the most zeal; and there
they were still opposed in the most formidable manner
by the Mahratta chieftain. Sevajee was at this time in
possession of all the ridge that stretches from Rajah-
poor to Damaun; besides which, he had several detach-
fed fortresses of great strength to the eastward. With
the exception of Chaul, he was in possession of the sea
cost from the river of Rajahpoor to the river Pener,
which flows into the harbour of Bombay. As it was
evident that he meant to attack either Surat or Aurun-
gabod, Aurengzebe's generals fixed their station at Jen-
niah-gur, which was the most proper point to watch
his movements in either direction. Sevajee, however,
eluded their vigilance, and at the end of the year 1669
he suddenly attacked and reduced Surat. This insult
increased the indignation of the emperor; but as he
could not spare more troops from near his own person,
he was obliged to dispatch them into the Decan even
from the province of Bahar. He also resolved to make
a descent on the shores of the Conan, and thus com-
pel Sevajee to attend solely to the defence of his own
dominions. Against the fleet which was to be employ-
ed in the transport of these troops, the Mahratta chief
sent one of his generals, in the hopes of being able to
destroy it in the harbour; but this expedition proved
unsuccessful. The plans of Aurengzebe, however, did
not restrain Sevajee; by his prudence and enterprise,
he gradually enlarged his territories, and more firmly
established his power.

In the mean time, the rebellion of the Patans of Ca-
bul had become the most solstitial concern of the em-
pire. One entire army, commanded by the Mogul's
governor of Feshawer, which had crossed the Indus, was
destroyed by them. Encouraged by this success, they
became more daring, and formed a plan which might
have proved fatal to the power of Aurengzebe. It has
already been mentioned, that the emperor's brother Su-
jah took refuge with the rajah of Arranak, by whom
he was murdered. It happened that a Patan soldier,
who had served in the army of Sujah, bore such a re-
semblance to him in countenance and figure that they
might easily have been mistaken for each other. This
man had also acquired the manners and deportment, as
well as some minute particulars of the life of Sujah, in
a surprising degree. This adventurer the Patans produ-
ced as the lawful king of Hindostan, and all the tribes
were summoned to march with him to Delhi. As they
could bring 150,000 men into the field, and were brave
and active, and retained an hereditary aversion to the
Mogul authority, this intelligence alarmed Aurengzebe,
and schemes of distant conquest were laid aside for the
protection of his throne. As he was not a man either
disposed or obliged to be dilatory in his movements,
he immediately displayed the standard of the empire,
marched from Delhi in April 1674, and crossed the
Indus at the end of the year. The particulars of this
expedition are not clearly or fully detailed; but it ap-
pears that the rebellion was soon quelled, and the Pa-
tans, though not completely subdued, were compelled
to retire to their mountains, and the emperor returned
to his capital in July 1676.

Towards the Decan, and the designs of Sevajee, he
again directed his anxious attention. The Mahratta
chief was still carrying on his conquests, and had even
penetrated into the Carnatic. While Aurengzebe was
engaged in warfare with the Patans, he was obliged to
pass unnoticed, and unpressed the schemes of Seva-
jee; and he probably thought, that he would waste his
force unprofitably at such a distance, against so strong
a country. But he was mistaken in this idea; for Seva-
jee was not only able to maintain his conquests, he
also, by the prudent and economical mode in which he
conducted his wars, drew from that conquest the means
of other invasions. Vissiapore now became as much ex-
posed to his attacks from the Carnatic on one side, as
from the Conan on the other; and the rich countries
to the south of the Coleroon lay at his mercy.

Aurengzebe intended to have put himself at the head
of his armies in the Decan, having found that his ge-
nerals were not equal to the Mahratta chief in
talents or skill; but his persecution of the Hindoos
had stirred up the Rajpoot tribes in Ajmeer, and he
deemed it necessary, in the first place, to reduce them.
Accordingly, he advanced towards their country in the
year 1678. On the approach of his army, they aban-
donned the plain, and secured their herds, and their
women and children, in the vallies within the mountains.
Aurengzebe, insensible of the dangers he was about to
encounter, and ignorant both of the nature of the coun-
ty, and of the resources and army of the rajahs, pushed
on in the most imprudent manner, till at length the di-
vision, which he himself commanded, was unexpected-
ly stopped by insuperable defences and precipices in
front; while the rajahs, in the course of one night,
passed the passes in his rear, by filling the overhanging
trenches, and from their stations above prevented all
endeavours of his troops to remove the obstacle. The fa-
vourite wife of the emperor, who had accompanied him.
in this war, was inclosed in another defile of the mountains, where she was taken prisoner. The emperor himself, unable to escape and unwilling to surrender, was exposed to all the horrors of famine; but most unexpectedly and unaccountably, after being thus confined for two days, the rajahs withdrew from their stations, and permitted him to escape. The empress also was sent back; and the only recompense which the rajahs asked in return for this moderation was, that the emperor would refrain from destroying the sacred animals of the Hindoo religion; but he ascribed their forbearance to fear of future vengeance, and continued the war. Being, however, a second time exposed to imminent danger, he resolved to leave the conduct of the campaign to his sons Azim and Acker, while he himself retired to Ajmeer, with his body-guard of 4000 men. His sons continued the war each in a different part of the country; but neither, at the end of the year, had been able to force the passes of the mountains.

We must now return to the Decan. Sevajee, in consequence of a confederacy of princes against him, had been compelled to retreat; but his spirits were not broken, nor his plans frustrated. He soon resumed offensive measures, and was again successful in a most important enterprise. A convoy of money for the use and support of the Mogul army was coming to Aurungabad, of which he received early intelligence. He resolved to intercept it; and accordingly, with a detachment of his best cavalry, he set out, and fell upon the convoy, before his approach was known, within a few miles of Brampropore. He seized and carried off the whole; but the excessive fatigue which he had undergone in this rapid march, produced an inflammation of the breast. His illness was concealed as long as possible, but it proved fatal on the 5th of April 1680. At the period of his death, the Mahrratta states comprised, on the western side of India, all the coast, with the back country, from the river Mirzeen to Varsal, excepting the small territory of Goa; to the south, Bombay, Salsette, and the Portuguese possessions between Bassein and Damman; to the north, along the other side of the ridge, they comprehended all the districts as far as the mountains continued to the westward. The length of the whole might be estimated at 400 miles, and the breadth at 120. At the distance of 300 miles from this territory he was in possession, towards the eastern sea, of half the Carnatic. The whole had been acquired by his own abilities and enterprise; and he left, at his decease, a permanent sovereignty, established on communion of manners, customs, language, and religion.

Aurengzebe could not restrain the emotions of his joy on hearing of Sevajee's death, nor the justice due to his character, which he had denied him during his life. "He was," he said, "a great captain; and the only one who had the magnanimity to raise a new kingdom, whilst himself had been endeavouring to destroy the ancient sovereignties of India." He added, that his armies had been employed against him for 14 years, and nevertheless his state had been always increasing. He was accustomed to apply to Sevajee the appellation of the Mountain Rat.

Aurengzebe still remained at Azim directing the war against the Rajpoots, carried on by two different armies, under the command of his sons. In the year 1681, the army of Azim took the city of Chittore by surprise, where all the favourite objects of Hindoo worship were destroyed. The rajahs, however, were not dispirited, and Aurengzebe deemed it prudent to recall his armies from the Decan. The whole force of the empire, which could with prudence be collected to one spot, was now employed against the two Rajpoots, under the command of the three sons of the emperor, and his own inspection. Of these sons, the youngest, Acker, was turbulent, arrogant, and mischievous. The army he commanded lay nearest the city of Ajmeer, where Aurengzebe was; and Acker was easily bribed by the promise of the support of the Rajahs, to attempt the seizure of his father, and the placing himself upon the throne. The scheme, however, was betrayed to Aurengzebe, and Acker judged it prudent to escape and take refuge near Gazerat. Mauzum, the eldest son, was ordered by Aurengzebe to follow Acker, and not to quit the pursuit till he had taken him: the fugitive, however, effected his escape; and on the 1st of June 1681, arrived at Pawleegur, a fort at the foot of the Ghaus, not far from Bombay.

Sambagee, who had succeeded Sevajee as chief of the Mahratta, was at this time at Pandu; and shortly afterwards he paid his personal homage to Acker, declaring that he intended to accompany him with 30,000 horse to Brampropore, and there proclaim him emperor of the Moguls.

Aurengzebe, when he learnt that his son had effected his escape into the south of India, fully impressed with the necessity of prompt and vigorous measures, sent forward the two armies commanded by his sons, and soon afterwards marched from Ajmeer with a third army, which he himself commanded. Before he set out, however, he concluded a peace with the Rajpoots; by which he agreed to surrender the district of Meirdah, which had been taken from Chittore by Shah Jehan; and the emperor, on his part, did not insist on the capitation tax—the constant source of uneasiness and turbulence with the Rajpoots.

By the middle of November 1681, the three armies had arrived at their intended stations. Azim's at Ahmednagur, Mauzum's at Aurungabad, and Aurengzebe himself at Brampropore. His plan was to attack the mountains with his land forces, while his fleet should act against the fleet and coasts of the Mahratta chief. This war is full of petty details, rather than of interesting and important transactions. Sambagee continued for a long time either to resist the open measures, or to frustrate the secret designs of Aurengzebe, till at length, in 1689, he was betrayed into his hands, and murdered in the most barbarous manner by his orders. Prior to this event, Aurengzebe had commenced hostilities against the kings of Jepore and Golconda, and he had reduced these two countries completely under his power; but notwithstanding these successes, and the death of the Mahratta chief, the mountainous parts of Baglana were unsubdued, and he experienced great difficulty in procuring his conquests on the west.

His absence for so long a time in the Decan, encouraged the tribes in the north of his empire, particularly the Rajpoots, Patans, and Jats, to take up arms: this was the first time that the Jats appeared otherwise than as banditti. These insurgents, however, were soon and easily quelled; and the emperor appears to have passed the remainder of his reign unmarked by any event of moment. He died in the year 1707, in his 90th year of his age, after a reign of 52 years. Aurengzebe, under him, the Mogul empire reached the utmost limits to which it ever attained; it comprehended the country from the 10th to the 35th degree of latitude, and nearly as many degrees of longitude.

Notwithstanding the ambitious projects in which Aurengzebe was engaged during a large portion of
his very long reign, he was by no means unattentive to the improvement of his empire, or the comforts of his people. He uniformly, and without solicitation, remitted the taxes in those districts which suffered from a scarcity, inundation, or the ravages of war. And during his repeated journeys through every part of his immense empire, he carefully noted the farms which were cultivated in the most careful and productive manner; and, as a reward to the farmers, he either remitted or lightened their taxes. He built colleges in all the principal cities of Hindostan, and schools in the inferior towns. He likewise established several public libraries, and gave rewards to learned men. Hospitals, caravanseries, and bridges, were built, and where it was impracticable to build bridges, ferries were established. The administration of justice was impartial; and though severe and cruel in many of his measures of foreign or general policy, he was by no means so in the internal administration of his empire. So averse was he, either from feeling, principle, or policy, to punish crimes with death, that capital punishments were nearly disused during his reign.

His person was by no means remarkable; nor was his countenance handsome; but his features were marked with strong expressions of intelligence, and they were by no means disagreeable. His manners were prepossessing and simple, his voice was harmonious, and he was a good orator, and an elegant writer. He was well acquainted with the languages of Arabia and Persia, and he wrote the Mogul tongue, as well as the various dialects of India, with ease and elegance.

His wealth was immense. His revenue exceeded £80,000,000 sterling, in a country where the products of the earth are about four times as cheap as in England. Even after many years of weak government, and both public and private disturbances, Nadir Shah, when he invaded India, carried back with him from the royal treasury of Delhi above £80,000,000 Sterling in gold and jewels; most, if not all of which, must have been collected by Aurengzebe. Yet notwithstanding the immense wealth which he left behind him, the magnificence of his court was unrivalled, even in the annals of the East. His own dress was simple, except on days of festivals, when he wore cloth of gold and jewels. In the manners and habits of his private life, he was free from parade and ostentation, but he encouraged magnificence in his nobles, and required it in the governors of his provinces.

He rose every morning at day-break; and after going into the bath, he spent half an hour at his devotions, and the same time in reading. He then dressed. At seven o'clock, he went to the chamber of justice, where he expected to meet his judges. Here he heard appeals from such of his subjects as thought themselves aggrieved, and overlooked the last decisions of the courts of law. At this time every person was not only admitted, but encouraged, to approach him. To those who were poor and necessitous, he gave money, having always a large sum lying on a bench beside him for that express purpose. If a well-grounded complaint was made against any of his nobles, though they might be men of great influence and consideration, or even his personal friends, they were deprived of their estates, and thus degraded, were obliged to appear daily at the hall of audience, till they were restored to their rank and property, by offering full redress and compensation to the injured party; but, if they continued contumacious, they were banished. At nine o'clock, the emperor breakfasted with his family; after this he appeared at a balcony facing the great square of his palace. The elephants were now brought out, richly caparisoned, as well as his state horses, to be reviewed before him;--acts of horsemanship and combat of wild beasts took place. At eleven o'clock he went to the hall of audience, and mounted a throne covered with jewels; before him all his nobles, in two ranks, were arranged, on rich carpets, when the ambassadors, viceroys, generals, and visitors, were introduced. Each person on being presented, made an offering; and if he was in high favour, the king received it from his own hand. The ceremonies of introduction consisted in bowing three times, at three different intervals, on approaching the throne, and the same on retiring. When a new dignity was conferred on any noble, a dress of state, two elephants, two horses, a camp-bed, a sword, warlike instruments and ensigns, his patent, and a sum of money, were given him by the emperor. The hall of audience was a most magnificent and splendid apartment; its roof was of silver; the rails which divided it from the courts were of gold, and the other rails of silver. It opened into a large square, where Aurengzebe reviewed his troops. A second square was occupied by the lower order of nobility; a third by artisans, who came to exhibit their manufactures, and who received rewards according to their merits; and a fourth was filled by huntsmen, who presented wild animals and game. The emperor spent two hours in this hall, after which he retired to his bathing chamber with his officers of state, and regulated the common affairs of the kingdom. He spent an hour at table, and in the hot season slept half an hour after dinner. At four o'clock he appeared in the balcony over the great gate of the palace, when a mob usually collected round him with petitions and complaints. From this he retired to prayers, and thence to the bathing-room again, where the vizier and other ministers assembled. The council frequently sat late, but the usual hour for the emperor's retiring was nine o'clock.

Such was the mode in which Aurengzebe spent the day while he was at Delhi, as described by Bernier. Even when he was on a journey, the court of justice was held in the camp; at the same hours as in the city. But as it might have been inconvenient, or beyond the means of many, to follow the king for the sake of obtaining justice, to these was granted a sum adequate to defray their travelling expenses.

That most curious traveller, Bernier, who followed the camp of Aurengzebe from Delhi to Cashmere, describes, with great accuracy, the immense moving city. The guard of cavalry consisted of 35,000 men, that of infantry of 10,000. It was computed that the camp contained 150,000 horses, mules, and elephants; 50,000 camels; 50,000 oxen; and between 300,000 and 400,000 persons. Almost all Delhi followed the court, whose magnificence supported its industry.

Such is the picture of the magnificence and magnificence of the Mogul empire at the period of Aurengzebe's reign, when it had attained its utmost extent and splendour, and before the peculiarities of its manners were broken in upon by the intermixture of those of foreign nations.

Aurengzebe seemed sensible, before his death, that his empire, which had been extended so much by himself, by means not the most justifiable, and which was composed in a great degree of parts so discordant and distant, would, in all probability, not long remain quiet and undivided; and this apprehension was increased by his observation and experience of the character of
The two chieftains who had raised the emperor to the throne, thinking themselves slighted on account of his favourites, imprisoned him, after a reign of six years, in 1717, and placed one of the royal family, whom they released from confinement, in his stead; him they deposed and murdered, and also his brother. Thus in the space of eleven years from the death of Aurungzebe, five princes of his line who had mounted the throne, and six others who had been competitors for it, had been disposed of. The Seiks had the disposal of the seat of government, and nominally of the empire at large; but an irreconcilable anarchy had been introduced into all the provinces, the governors of which were strongly disposed not only to coincide with the Seiks in their want of allegiance to the head of the empire, but even to dispute the power of the Seiks themselves.

In the year 1720, Mahomed Shah, grandson of Bahaunder Shah, who since the accession of Jehaunder Shah had been in confinement, was placed on the throne by the Seiks. His first enterprise was against the Seiks themselves. Warned by the fate of his predecessors, he was convinced, that till they were reduced to the rank of subjects, he could not be emperor. As soon, therefore, as he had cautiously and gradually strengthened his own influence and power, he began to reduce theirs. But they had been too long the virtual rulers of the empire to submit quietly; and having numerous friends and partizans, they openly rebelled against their sovereign. A battle ensued, in which they were defeated, and their defeat was followed by the emperor's acquiring his full and legitimate power. But, in consequence of the agitated and disturbed state of the empire, the distant parts of it, especially those which had been added to it recently, lost their allegiance and dependence; particularly the Decan, of which Nizam ul Moolk was viceroy. This man having been afflicted by the Seiks while they were in power, resolved to avenge himself upon the emperor. He accordingly remained almost constantly at the seat of his government; and his measures while there created great suspicion and alarm. In order, if possible, either to tempt him from his plans, or to get him into his power, the emperor invited him to court, and offered him the situation of viceroy. But he was too enlightened and cautious, or too ambitious to accept of this offer. As, how-
ever, he was sensible that by himself he stood little chance of succeeding in his designs of rendering the Decani independent, he cast his thoughts round for assistance; and on many accounts the Mahrattas seemed to him best calculated to answer his object.

The power and territories of the Mahrattas had been gradually increasing. Enterprising and active, commanded by princes who in a high degree possessed these characteristics of the nation, and surrounded by weak and divided states, it is not to be wondered that they succeeded in gradually extending their dominions, and in striking awe into their neighbours. Early in the reign of Mahomed Shah, they had imperiously demanded and received tribute from him, under the condition that they would lay waste or seize the provinces of Malwah and Ajmeer; and this tribute amounted to one-fourth of the net revenue which be derived from these provinces. As might have been expected, however, they were not long satisfied with this tribute, for they invaded and conquered the greatest part of Malwah. A short time afterwards they seized upon the other part, as well as upon the province of Ajmeer. The Mahrattas, therefore, were by no means unwilling to listen to the proposal of the Nizam; but their object was not so much to assist them, as to benefit themselves; and they hoped, during the disputes and wars between him and the emperor, that they should be able still further to extend their territories.

In the year 1788, the Nizam, having arranged all his plans, and believing himself sufficiently powerful to carry them into execution, came to court attended by a large body of armed followers. He had already, by his intrigues and bribes, procured a large party there; but on his arrival he found that the opposite party was too strong for him. At the head of it was the commander in chief of the army of the empire. The Nizam had now gone too far to retreat, and as the Mahrattas, though acting with him in the middle provinces, could be of no use where support was chiefly wanted, he directed his thoughts to another quarter.

At this period Nadir Shah, the usurper of the Persian throne, had invaded the province of Candahar, and was besieging the fortress of Candahar itself. This province, which had long formed part of the Mogul empire, at this time was held by an Afghan chief. The siege lasted 18 months. After it was finished, Nadir prepared to invade Cabul. The Nizam, informed of these designs, resolved to invite Nadir to invade Hindostan. By some it is said, that it was in consequence of this invitation alone, that Nadir entered Hindostan; but according to others, while he was in Cabul, the imprudence of Mahomed afforded the Persian ambassador, and this afforded an immediate pretext for the invasion of his master. However this may be, in the year 1739, Nadir Shah entered into Hindostan.

A kind of infatuation seems to have prevailed in the Mogul councils. The army was not half assembled; and Mahomed had marched only a day's journey from Delhi into the plains of Carnawal, when Nadir, who had by this time reduced Lahore, defeated him, with the loss of Douran, the commander in chief of the army, and his best and bravest minister. It appears that before this fatal battle, Nadir was so little confident of success, that he offered to evacuate the empire for 50 lacks of rupees. But the intrigues of the Nizam and his party induced the emperor not only to refuse this sum, but after the battle to throw himself on the clemency of Nadir. The first consequence of the battle was the reduction of Delhi. At first the strictest discipline prevailed among the Persians; no one was molested; and the emperor, after having been kept a state prisoner with his family for a few days, was permitted to return quietly to his palace. But though this strictness of discipline was maintained, and this moderation with regard to the emperor, the conqueror was intent on plunder, and the scene was soon changed. A quarrel having arisen in the bazaar of Delhi; one of those engaged, suddenly called out that Nadir Shah was dead, and that now was the time to free Delhi from the Persians. A massacre instantly commenced; and during the whole night, the city was a scene of confusion and murder. The inhabitants, however, had seen ample and dreadful reason to repent of their precipitancy; for at daylight Nadir gave orders for a general massacre, without distinction of age or sex. The carnage lasted from sun-rise till mid-day, when the emperor and his nobles appeared before Nadir Shah, and, for the sake of Mahomed, he was induced to pronounce the words "I forgive." Instantly the carnage stopped, but its effects continued; for many Hindoos as well as Moguls, in order to save their women from pollution, had set fire to their houses, and burned their families and effects. These fires spread, and the city soon presented a most dreadful scene of ruins. The dead bodies occasioned a pestilential disorder among the comparatively few inhabitants that survived; and, as always is the case during the prevalence of any dreadful calamity of this nature, every species of crime and immorality was indulged in. In order to extinguish confessions of treasures, private murders were committed; the ties of friendship and blood were forgotten. The evil, however, was not yet at its height: famine was added to pestilence, murder, and plunder; and hundreds of persons, desperate, and hopeless of escaping from such accumulated distress, and unable to bear the sight of those whom they had loved and respected, either falling under it, or what was worse in their estimation, giving themselves up to the commission of every crime, put an end to their own lives.

At length, after having possessed of Delhi for about six weeks, Nadir left it; but he left it almost a desert; for it is said, that 100,000 of its inhabitants had been massacred by his troops, or destroyed by fire, pestilence, or famine. A treaty had been concluded, by which he confirmed Mahomed on the throne of all the provinces east of the Indus, reserving those to the west for himself. He also married his son to a grand-daughter of Aurungzebe. He carried with him three millions and a half sterling in money from the royal treasury; one million and a half in plate; fifteen millions in jewels; the celebrated peacock throne valued at a million; other thrones of inferior value; and the canopy for the royal elephant, estimated at eleven millions; besides 500' elephants, a number of horses, and imperial camp equipment. A fine to the amount of five millions was exacted from the nobles and other inhabitants; so that, if to these sums be added the plunder of the soldiers, the estimate that 62 millions were carried away, will not be deemed beyond the truth.

No empire, after such devastation committed in its capital, could soon have recovered its strength; but with respect to the Mogul empire, its restoration was absolutely impossible. It was loosened from its foundation; and there were those on every side of it, who were prepared to hasten its downfall. The departure of Nadir left the Nizam in possession of the whole remaining power of the empire; but he preferred an independent kingdom in the Decan, to the government
of a feeble and declining state. About this time, Bengal became independent of Delhi, under Aliverdy Cawn, (see Bengal); and not long afterwards, a vast army of Maharrt胛, both from Poonah and Barar, for they were now divided into two states, invaded it, under the pretense that their object was to recover it for the emperor. The Mogul empire now became a prey to all the neighbouring states that were sufficiently contiguous and powerful to attack it. The Rohillas erected an independent state on the east of the Ganges, within 80 miles of Delhi.

They were originally an Afghan or Patan race, who emigrated from the province of Cabul about the beginning of the 15th century. They then consisted of several independent tribes, who acted in concert when necessary, and were remarkable for the hatred which subsisted between them and the Maharrtillas. About the year 1720, the Afghan chiefs Bisharat and Daod, accompanied by a great number of their countrymen, came into Hindostan in quest of military service. Here they established themselves. Daod was succeeded as their principal leader by Ali Mahomed, under whom, taking advantage of the distracted state of Hindostan, they acquired the territory which has been mentioned, to which they gave the name of Rohilcund.

In the years 1740 and 1741, the Maharrtillas invaded the Carnatic: and the intelligence of these invasions hastened the departure of the Nizam from Delhi to the Decan; for the Carnatic was included in his government, and he was anxious to recover it. Before however he left Delhi, he delegated his power at court to his eldest son. On his arrival in the Carnatic, he succeeded in settling it for the present; but this part of the Mogul empire was now not only really but nominally rendered independent.

In the year 1747, Nadir Shah died; and in the confusion which followed, Abdalla Ahmed Shah, a soldier of fortune, who had been raised to high rank by Nadir, seized on the eastern part of Persia, and on the contiguous provinces of India, which had been ceded by Mahomed to Nadir. These he formed into a kingdom, and united it to Cabul, of which he had also made himself the chief. The provinces thus wrested from the Mogul empire, nearly comprised the ancient empire of Ghzani. In the year of this invasion of India by Abdalla, Mahomed Shah died, after a reign of 29 years. Though by no means qualified either in talents or habits for the turbulent times in which he lived, he seems to have been a humane and respectable prince.

He was succeeded by his son Ahmed Shah. Before his accession, he had manifested many proofs of spirit and bravery; but scarcely was he seated on the throne, when he disappointed his subjects, by giving himself up entirely to dissipation and pleasure. His reign, which lasted about six years, was a scene of confusion, owing to the turbulence of the nobles, and the inursions of the neighbouring powers. Before he died, the entire division of the remainder of the empire took place, nothing remaining to the house of Timur except a small territory round Delhi, together with the city itself; and this was constantly exposed to depredations, massacres, and famines, by the contents of invaders. The last united army was defeated by the Rohillas in the year 1749; and the result of this defeat, was the complete establishment of the independence of the Rohillas in the eastern part of the province of Delhi.

The Gants, a Hindoo tribe, established themselves, and founded a state in the province of Agra. This tribe attracted notice in Hindostan for the first time about the year 1700. At this period, having migrated from the banks of the Indus into the lower part of the province of Moultan, they were permitted to settle in several parts of the Doob of the Ganges and Jumna. They were then agricultural, but they soon afterwards became a warlike tribe; and their subsequent progress was uncommonly rapid. During Aurengzebe's last march towards the Decan, one of their leaders pillaged the imperial baggage, and, with part of the spoil, erected the fort of Bhurtpoor. Afterwards they erected other forts, from which they made incursions into the neighbouring territories; and during the civil wars carried on by the successors of Aurengzebe, they found means to secure themselves a large portion of country, and accumulated great wealth.

It may be proper to point out particularly the fate of those provinces, which once constituted the Mogul empire, at this period. The Decan was usurped by its viceroy the Nizam; and Bengal by its viceroy Alliverry. Oude, which at an early period of the Mahomedan invasion had been subdued by the invaders, and had remained under different vicissitudes attached to the throne of Delhi, was seized upon by Seifdar Jung, the nephew of Saadet, who had been appointed soudbdar of this province during the reign of Mahomed Shah. Allahabad was seized by Mahomed Kooli. Malwab, which had been invaded and overrun by the Maharrtillas in the year 1707, was finally separated from the Mogul government about the year 1732, and was divided between the Poona Maharrtillas, and several native princes and Zemindars; the Maharrtillas also possessed the greatest part of Guzerat, Berar, and Orissa, besides their ancient territories in the Decan. Ajmeer had never become a regular organised possession of the Mogul empire like Agra and Delhi; but remained in a kind of half independent state, paying a tribute, and furnishing the imperial armies with a certain number of mercenaries. After Aurengzebe's death in 1707, it continued for some time under a nominal subjection to the Delhi throne; but about the year 1748 it assumed total independence, and reverted to its ancient masters the Rajpoot princes. The Seiks also took advantage of the weakness of the Mogul empire, and in 1746 made themselves masters of a considerable part of the Doob of Ravey and Jallinder. In fact, to use the words of Major Rennell, "The whole country of Hindostan proper was in commotion from one extreme to another, each party fearing the machinations or attacks of the other; so that all regular government was at an end, and villany was practised in every form. Perhaps in the annals of the world, it has seldom happened that the bonds of government were so suddenly dissolved over a portion of country, containing at least 60 millions of inhabitants."

In 1748, the Nizam died. His eldest son still remained at Delhi; and his second son Nazirjung, taking the Nizam, advantage of his brother's absence, ascended the throne. A.D. 1748.

At this period, the French and English first appeared in a military character, as auxiliaries of the princes of Hindostan, in consequence of the wars respecting the sovereignty of the Decan, and for the nabobship of Arcot. In the first, the French only interferred; in the latter, both nations. These wars lasted till the year 1754, and terminated after much blood had been spilt both in battle and by assassination, in fixing Mahomed Ali in the government of Arcot, and Salih, the eldest of the sons of the Nizam, in the government of the Decan. Although the power of the Mogul emperor had long ceased to be of political consequence, yet his name still held in respect,
and person were of use, as retaining a considerable degree of veneration among the mass of the people, not only in Hindostan proper, but also in the Deccan; so that application was made to him to sanction and confirm all grants of lands, even in those districts in which he retained no sovereignty, in order to reconcile the transaction to popular opinion. Even to this day, the coin throughout the whole district, known by the name of the Mogul empire, is struck in the name of the nominal emperor.

In the year 1753, the emperor Ahmed was deprived of his eye-sight, and deposed by Gazi, the son of that Gazi who had been his vizier. A little before his death, the Maharratts had been called in to assist in reducing the Gouts, who being in possession of Agra, were troublesome to the emperor; and the Maharratts of Berar established themselves in Orissa, by cession from the Nabob of Bengal, who was also compelled for a short time to pay them a tribute for Bengal and Bahar; on this tribute they long afterwards rested their claims in these provinces. On the death of Ahmed, Alumghire his cousin was placed on the throne by Gazi; the new emperor soon found that he was a slave in the hands of this person, and in order to get rid of him, he invited Abdallah, commonly called the Durrancé Shah, who was at this time in possession of Lahore, to Delhi. He gladly accepted this invitation, and laid that city under heavy contributions, not even sparing the sepulchres of the dead. From Delhi he proceeded against Agra, but the Gouts repulsing him, he returned towards Cundahar in 1758. The situation of the emperor was now most deplorable; he could not possibly retain the small remnant of an authority which was left to him, without foreign assistance; and yet if he invited foreigners, they only defended him against internal commotion and intrigue, for the purpose of plundering him, and laying waste his territories. Thus he was alternately treated by the Maharratts and Abdallah, according as he called in the one or the other to his assistance. A little before he was murdered by his vizier, Abdallah again visited Hindostan, when Delhi was plundered and almost depopulated. At this period his son Shah Allum was engaged in a fruitless attempt to reduce the Bengal provinces. As soon as he ascended the throne, he followed the example of his father, and successively threw himself for assistance on the Maharratts, Nedjel Dowlah, a Rohillah chief, who commanded the Mogul army in the time of his father, and Sujah Dowlah, another powerful chieftain: by these, however, he was either not assisted, or assisted only to be still more plundered and insulted; at length, he was received under the protection of Mahomed Kooti of Allahabad. This chief, in conjunction with Balvant Singh, who had increased the Zemindary of Benares, which he had received from his father, to the size of a province, supplied him with an army; with this he entered the Bengal provinces, where he was joined by some Zemindars of Bahar, so that his force altogether amounted to about 60,000 men. But his troops were so ill disciplined and provided, that in the year 1761 he deemed it prudent to surrender himself to the British, who were then acting as allies of the Nabob of Bengal. They however were not disposed to connect their fortunes with his; and he was again obliged to put himself under the protection of Sujah Dowlah.

Abdallah, in the mean time, was by no means secure in his possessions; for the Maharratts, who, in the midst of these confusions, had been daily gathering strength, and being engaged in every scene of politics and warfare from Guzerat to Bengal, and from Lahore to the Carnatic, resolved to attempt the expulsion of Abdallah from Hindostan. Thus the principal powers in it were arranged in two parties, the Hindoos and Mahomedans, for the Gouts joined the Maharratts, while Sujah Dowlah, with the Rohillas, and other Mahomedan chiefs, joined Abdallah. The battle, which was to determine whether the Hindoo government should be restored or not throughout Hindostan, was fought on the 7th of January 1761, on the plains of Panipat, already famous for having been the scene of a battle between the Sultan Baber and the Patan emperor Ibrahim in 1525.

The combined Mahomedan army was commanded by Abdallah, and that of the Maharratts by Sedasiva; the former consisted altogether of 42,000 horse, and 38,000 foot, besides camels, and between 70 and 80 pieces of cannon; these were the regular troops, but the irregulars were more numerous. The Doorannisses of Caubul, who were the strength of the army, amounted to 29,000; they were all men of great bodily vigour, and their horses, which were of the Turkish breed, were very hardy. The regular troops of the Maharratt army consisted of 55,000 horse, and 15,000 foot, with 200 pieces of cannon, and camel pieces and rockets without number. Besides the regular troops, there were 15,000 pindaries or plunderers, and the followers of the camp were nearly four times as numerous as the regular troops.

The strength of these armies was too nearly equal, and the issue of the battle too momentous, not to excite in the generals of both parties great anxiety, and to render them cautious and reserved about commencing the engagement. Accordingly, they continued in sight of each other from the 20th of October 1760, to the 7th of January 1761. During this long interval, many bloody skirmishes took place, which generally terminated in favour of the Doorannisses. At last the Maharratt army, being greatly straitened for provisions, their chieftain resolved to quit his entrenchments and give battle. The action continued from morning till nearly noon, without any decisive success on either side; but about this time the Maharratt chief's son, a youth about 17, being mortally wounded, the fate of the battle was decided; for after this event, the Maharratts fled in all directions. The victors pursued, and gave no quarter in the heat of the pursuit.

In the Maharratt camp, it is said that there were of all descriptions, men, women, and children, about 500,000, of whom the greatest part were either killed, or taken prisoners; and of those who escaped from the field of battle, many were destroyed by the Zemindars. About 40,000 were made prisoners; such as were taken by the Doorannisses were mostly murdered afterwards by them; for this carnage in cool blood, they alleged as an excuse, that when they left their own country, they were requested by their mothers, sisters, and wives, to kill some of the unbelievers on their account, in order that they also might possess a merit in the sight of the prophet. The commander-in-chief of the Maharratts is supposed to have been killed, either in the battle or in the pursuit. This was the most important struggle that had taken place since the contests between Aurengzebe's sons in the year 1707.

After this very decisive battle, Abdallah with justice regarded himself as the uncontrolled master of Delhi;
but as his policy was to rule there in the name of the lawful emperor, he invited Shah Allum to return thither, promising to seat him on the throne of his ancestors. This invitation, however, was not accepted; and Abdallah, in order to secure to himself the attachment of the people as far as he could, set up Shah Allum’s son, under the protection of Nidjib Dowlah, exacting at the same time an annual tribute. It is highly probable that he meant afterwards to have changed the dynasty, and to have established himself on the Mogul throne; but his presence was required in Lahore, where the Selkis threatened to overpower his garrisons. Scarcely had Abdallah left Delhi, before the small portion of territory which remained to the Mogul emperor, consisting merely of the northern part of the province of Delhi, was invaded both by the Gurs and the Mahrattas; but Nidjib Dowlah, under whose guardianship Abdallah had left Shah Allum’s son, either baffled them or bought them off.

We have been induced to carry the history of Hindostan rather beyond the limits which we fixed to the first division of this article, in order that we might embrace as many of the events of that history as possible, which did not mainly or directly depend upon the principle or auxiliary operations of the Europeans; but from the period to which we have brought it down, the Europeans acted such an important part in Hindostan, that it will be proper to consider them, and especially the British, as the pivot on which its future history turns. This, therefore, leads us to the second division of this article, in order that we may trace the rise and progress of that power which, proceeding from the western extremity of Europe, established such a vast empire in Hindostan.

PART II.

RISE AND PROGRESS OF THE EUROPEAN ESTABLISHMENTS IN INDIA.

As the Europeans were induced to form their establishments in India, in order to be nearer the source, and have a more ready and complete command of those luxuries which, for many centuries before the formation of these establishments, had become in such high and general request in the western world, it may be proper to introduce this part of our subject by a rapid glance of the commerce of the ancients with India, and of the means and route by which these luxuries were introduced into Europe before the discovery of the Cape of Good Hope.

Of all the nations of antiquity, the Phenicians were the most enterprising and extensive in their commerce. Having obtained possession of Eziongeber, and other parts at the head of the Arabian Gulf, they were enabled to keep up a regular intercourse with India and the east coast of Africa. At first they were obliged to convey their merchandise from the ports of Ithome to Tyre; but having acquired Rhinocorura, the present El Arisch, the nearest port of the Mediterranean to the Arabian Gulf, they brought the produce and manufactures of India to this port, and thence conveyed them by sea to Tyre. This was one of the most ancient routes of communication between the western parts of Asia and India. Another route, which seems also to have existed from the earliest times, was by the Persian Gulf through Mesopotamia, the coast of Syria and Palestine. Besides these two routes, two others were pursued by the ancients, by the Caspian and Black Seas. The first route, according to Strabo, was as follows: The productions of India having been collected at Papatla, the present Tatta, near the mouth of the Indus, were carried up this river as far as it was navigable; and thence they were conveyed by caravans to the Oxus, Ghion, where they were again sent by water, and descended this river as far as the point where it most nearly approaches the Ochus, Tedjen. To this latter river they were conveyed by caravans. The Ochus brought them to the Caspian Sea, across which they were embarked to the mouth of the Cyrus, Kur; up this river they were carried to its nearest approach to the Phasis, Itoni, where caravans were again employed to convey them to Sarapana, Schoroban, a town on this river. The communication between this place and the Black Sea, by the Phasis, was easy and short. In some instances, it appears that the merchandise of India was carried down the Oxus till it arrived at Lake Aral, into which that river falls; and, being transported across this lake, was sent in caravans to the Caspian. The Wolga was next ascended, to the point where it approaches nearest to the Tanais or Don; to which latter, crossing by land, the merchandise was carried down to the sea of Azoph. The fourth route, according to Strabo, was across the Caucasus from the Caspian to the Black Sea.

Such were the routes by which the merchandise of India arrived in Europe, prior to the time of Alexander’s invasion of that country; but he determined, as soon as he became master of Egypt, to found a city which should not only eclipse Tyre, but carry on a more direct and easy intercourse with India than had been formerly done. The Romans had not been very long established in Egypt, before, having acquired a knowledge of the monsoons, they perceived that, by taking advantage of them, a more direct communication with India might take place. Their merchants, accordingly, ascended the Nile from Jullianopolis, about two miles from Alexandria, to Coptos. Hence they transported their goods in caravans to Berenice. Here they arrived in the middle of summer; and immediately embarking, reached the coast of Osellis, Gallas, on the east coast of Arabia Felix; thence they coasted to Musiris, Meryce, on the west of India. It is probable that some of their navigators even doubled Trabonane, Ceylon, and ascended the Ganges to Patalabraham, at that time the most commercial city in India. They returned from India with the north-east monsoon, performing the shorter voyage within the year.

The great mass of the commerce between India and Europe was carried on in the same route of the Red Sea, till the seventh century, when the conquest of Egypt by the Saracens transferred it by the Black Sea to Constantinople. As soon, however, as the Mamelukes became masters of Egypt, they permitted the Venetians to follow the ancient route; and when De Gama displayed the Portuguese flag in the Indian seas, Alexandria was the sole entrepot of Indian commerce.

Having thus traced the various routes of communi-
Sociation that existed before the discovery of the Cape of Good Hope, we shall subjoin an enumeration of the principal articles which the ancients brought from India.

1. Spices and aromatics. These were in great demand, not only as articles of high and expensive luxury, but also for religious purposes; of course, the ancients required a regular and immense supply of them; but there is reason to believe that they were brought principally, if not entirely, from Arabia; though it is probable that the Arabsians obtained them from the western parts of India; as at present the extensive demands of various provinces of Asia for these articles, especially for frankincense, are supplied by the Arabians from India.

2. Precious stones and pearls. Of these India furnished the chief part to the luxury and extravagance of the Roman emperors; and its productions of this kind were allowed to be most abundant, diversified, and valuable.

3. Silk. As the ancients had no direct communication with China, all the silk which they obtained, was purchased in India, whether it was brought in ships of the country.

Arrian, in his Periplus of the Erythraean Sea, has given us some minute and curious particulars respecting the homeward and outward cargoes of the ships employed in his time, in the Indian trade; they imported into Patala, on the Indus, woollen cloth of a slight fabric, linen in chequer work, some precious stones, and some aromatics unknown in India, coral, storax, glass vessels of different kinds, some wrought silver, money, and wine. In return for these, they obtained spices of various kinds, sapphires and other gems, silk stuffs, and silk thread, cotton cloths, and black pepper. Patala, however, was not the only, or the principal port, which the ancients frequented in India; the chief emporium of trade was Baragaza, which seems to have been situated on the river Nerbuddah. The articles of exportation and importation here were very various and numerous; besides those already mentioned, there were imported brass, tin, lead, girdles or sashes, mertilot, white glass, arsenic, black lead, gold and silver coin. Among the exports there were the onyx and other gems, ivory, myrrh, various kinds of cotton goods, both plain and ornamented, and long pepper. The exports from Musiris, which lay nearer the eastern parts of India, were still more rare and valuable. Arrian specifies particularly pearls in great abundance, and of extraordinary beauty, a variety of silk stuffs, rich perfumes, tortoise shell, different kinds of transparent gems, especially diamonds, and pepper in large quantities, and of the best quality.

As the demand for these, and other articles the produce or manufacture of India, increased along with the increasing civilization and wealth of Europe, the commerce of India was always an object of great importance with all those states of Europe which applied themselves to trade. Hence the rivalryship of Venice and Genoa respecting it; and hence the attempts which were made to reach the East Indies by sea. At length the Cape of Good Hope was discovered and doubled; and the Portuguese opened this easy communication with India.

After a tedious course of voyages, continued for nearly half a century, Vasco da Gama, an active and enterprising Portuguese admiral, doubled the Cape of Good Hope, and coasting along the eastern shore of the continent of Africa, sailed from thence across the Indian Ocean, and landed at Calicut on the coast of Malabar, on the 22d of May 1498. At the period of the arrival of the Portuguese in India, the west coast of Hindostan was divided between two great sovereigns, the kings of Cambay and the Zamorin; each of whom had under him numerous petty princes; at the same period the maritime region on the gulf of Bengal was divided into three sovereignties; 1st, That of Acrean, or Ilokhang, from the Ganges to Cape Negrais; 2d, Pegu or Bagao, from the Cape to Martaban; and 3d, Siam, from the latter to Tanasseri, near which the Malay peninsula begins. The dominions of the Zamorin included the whole coast from Bombay to Cape Comorin; Calicut was the capital, and one of the most commercial cities in India. De Gama, having received information of the riches of this city, immediately proceeded thither, and was on the point of concluding a commercial treaty with the Zamorin, when his object was defeated by the jealousy of some Mahomedan merchants; soon after this, he returned to Lisbon. Cabral was next sent out by the Portuguese court to Calicut; but the Moors were as little favourable to him as they had been to De Gama, so that he judged it prudent to proceed to Cochin and Cannanore. As the kings of these places were under the yoke of the Zamorin, which they were desirous of throwing off, they received him very favourably, and entered into alliance with him. The Portuguese thus in a short time acquired so great an influence, as to give law to the whole coast, fixing their own prices on the productions of the country, and building forts in the principal towns.

In 1508, Albuquerque arrived in India, and took the Goa taken chief command of the Portuguese; hitherto they had by them, not acquired a good port; and as this was an object of A.D. 1508, the first consequence, he attacked Goa, and took it with little difficulty; he was, however, unable to retain it; for the natives besieged it so closely, that he was in a short time in want of provisions, and compelled to abandon it and retire to his ships. He did not, notwithstanding, give up his object; but returning in a few months, he took it by surprise, and fortified it in such a manner, as to render it quite impregnable by the forces of the natives. It now became the metropolis of the settlements of the Portuguese in India, from which they spread their conquests and their commerce over the Eastern seas.

As the Venetians had been deprived of the most Venetians abundant and certain source of their riches by the dis- jealo of them,covery of the Cape of Good Hope, and the subsequent commerce by sea between Portugal and India, they stirred up the Sultan of Egypt to unite with them in the attempt to drive the Portuguese out of India. This he was easily induced to do, as he also had felt the consequences of the Portuguese voyages to India, in the reduced receipt of the transit duties, which he had been accustomed to levy on all Indian merchandise passing through his dominions. Accordingly an Egyptian fleet, equipped principally with materials supplied by the Venetians, made its way into the Indian sea, and being joined by the fleet of the king of Cambay, attacked the Portuguese, at first with some success; the latter, however, having received reinforcements from Portugal, soon regained their superiority.

About the same time, the Portuguese, having gain- ed the command of the Red Sea, and the Persian Gulf, the commerce between India and Europe by these routes entirely ceased. Thus secure from competition on the western shores of India, they next turned their thoughts to conquests on the East. Ne- glecting the coast of Coromandel, which possessed no
ports, they passed on towards the regions beyond the Ganges, and the Malay peninsula, of the riches of which they had heard wonderful accounts from the merchants of Surat. Their conquests here, however, and in the Spice islands, do not fall within our notice. In the middle of the 16th century, they had become masters of the eastern coasts of Africa; of the two provinces of India; of the Moluccas; and of the trade to China and Japan; they seized every vessel that sailed on the Indian seas without their permission, ravaged the coasts, insulted the native princes, destroyed the temples of their religion, and established the inquisition at Goa. But in the midst of these abuses of their power, their settlements were divided and torn by factions; the tribute paid by one hundred and fifty princes of India, as well as the revenue derived from other sources, was squandered by individuals; so that the forts and the ships were in a very ruinous condition. In this state of things, the Portuguese empire in India must soon have fallen, had not Juan de Castro arrived as viceroy. But great as his talents and virtues were, and indefatigable and wise as he was in his endeavours to restore his countrymen to their former character, the task was beyond his powers; and the native princes, at last roused by the indignities and oppression under which they had so long suffered, and encouraged by the effeminacy and supineness of their oppressors, united in a league to exterminate them. In this object they would have succeeded, had not reinforcements arrived from Portugal at this critical moment, by the assistance of which, the attack made by the native princes on the Portuguese establishments in 1567 was repulsed. On the union of Portugal to Spain, which took place soon afterwards, in 1580, the former country lost nearly all her power and her establishments in India, in the manner which we shall presently describe. At this time they possessed the following places: Diu, Damacun, Choul, Bassein, Salsette, Bombay, and Goa; they had factories at, and influenced the governments of Dabul, Onore, Barelone, Mangalore, Canaree, Calicut, Cranganore, Cochin, and Quilon; they had also factories in the Bay of Bengal, at Masulipatam, Negapatam, and St Thomé, with commercial stations in the province of Bengal. All these possessions and establishments were independent of what they had in Malacca, the Eastern Archipelago, &c. At present the settlement of Goa, which still nominally remains to them, is almost wholly abandoned by the mother country, and its inhabitants scarcely speak their national language intelligibly. Their poverty is such, that women of the best families earn their subsistence by making lace or artificial flowers, and working muslin. The remaining Portuguese possessions are Damacun, a sea port in the province of Aurungabad, 100 miles north from Bombay; Dhilli in the island of Timour, and Macao in China.

The first commercial transactions of the Dutch, after they had cast off the Spanish yoke, were with the Portuguese. From Lisbon they procured the productions of India, to sell them again to the nations of the north of Europe. This trade, however, was put an end to by Philip II. when he became master of Portugal; and the Dutch then endeavoured to discover a passage by the north seas to China and India. This enterprise was unsuccessful; but, while engaged in it, Houtman, a native of Holland, confined in the prisons of Lisbon for debt, proposed to the merchants of Rotterdam, to reveal to them the knowledge he possessed of Indian navigation and commerce, provided they liberated him from prison. His proposal was accepted; and an association was formed, which sent out four ships to India under Houtman, in the year 1594. On their first arrival in the Indian seas, the Dutch and Portuguese had only occasional skirmishes; but a sanguinary war soon followed, which in the end totally destroyed the Portuguese power. The native princes, in these contests, generally took the part of the Portuguese, either from fear of the Dutch, or from other motives. The Portuguese also had another advantage, in their superior knowledge of the Indian seas. But the Dutch, on the other hand, were much braver, and more active—stimulated by stronger motives, and yet in the vigour of their republican enthusiasm. Besides, they received continual reinforcements from Holland; whereas, after the conquest of Portugal by Spain, the connection between the Portuguese settlements and the mother country was very much loosened, and the intercourse abridged. Spain, jealous of the prosperity of her newly acquired subjects, left the Indian settlements entirely to their own force. In the three years, 1620 to 1622, that Hernan de Albuquerque was viceroy, he never once received any letter of instruction or information from the court of Spain. The colonies, therefore, must have been supported entirely from their own resources, which involved them in a destructive war with the Dutch. Success was notwithstanding long doubtful; but the Dutch at last gained the ascendency. The Portuguese at first lost Malacca and Ceylon; and in the year 1660, they were driven from Macassar, Cochin, Canaree, and other settlements on the coast of Malabar. In 1669, the Dutch obtained permission from the native princes to establish factories at Negapatam, Sadras, Pulicat, and Bimlipatam, on the east coast of the peninsula. From this period, the affairs of the Dutch are so interwoven with those of the English in India, that we shall defer their future history till we come to treat of the establishments of the latter.

For several years after the Portuguese, Dutch, and English had penetrated to India, the French contented themselves with procuring its productions from the Portuguese and Dutch. In the year 1601, indeed, a Company had been formed in Brittany, which sent two ships to India; but they returned with cargoes barely sufficient to defray the expenses of the equipment and voyage; consequently the Company was dissolved. In 1633, another Company was formed; but as their enterprises were confined to the island of Madagascar, they do not fall within our plan. The attempt to colonize this island not succeeding, the French sent some ships direct to India, and established factories with the consent of the native princes. Their chief rendezvous at first was at Surat; but the Dutch and English united against them, and soon obliged them to abandon it. They next attempted to seize on Trincomalee; but in this also they were unsuccessful.

In 1672, a French force, commanded by M. de la Haye, landed at St Thomé, a sea-port contiguous to Malacca, formerly possessed by the Portuguese, but then belonging to the king of Golconda, and carried it by assault. War, however, breaking out the same year between Holland on the one side, and France allied with England on the other, a powerful Dutch armament, assisted by the armies of the king of Golconda, invested St Thomé by sea and land. After a skilful and obstinate defence, the town was reduced in September 1674; but the king of Golconda insisted on retaining the con—
quest. This occurrence is principally remarkable, as
noting not only the first appearance of the French on
the coast of Coromandel, but the origin of their power
in that quarter; for, from the wreck of their establish-
ment at St. Thomas, was formed their celebrated settle-
mant of Pondicherry, where a small district was ceded
by them to the native prince. At the beginning of the
18th century, their establishments consisted of Pondi-
cherry, with small and insignificant factories at Musa-
lipatam and Rajapore. Soon after this period, the his-
tory of the French and English nations in India are so
blended, that they must be considered together.

In the year 1716, the Europeans established in India
found themselves unexpectedly encountered by a new
and powerful rival; for there appeared off the coast of
Malabar two forty gun ships, under imperial colours,
which had been fitted out at Ostend. In the year 1720,
the East India Company, by whom these ships had
been fitted out, received a regular charter from the
emperor; and in 1733 they had established factories
at Ceylon, between Madras and Sadasamy, at Ben-
kibazar on the Hooghly. The Dutch, French, and
English immediately took the alarm; and in 1727, a
treaty was signed at Paris, by which the emperor pro-
mised to suspend the company for seven years. Before
the expiration of that term, he pledged himself, by the
treaty of Seville, to the dissolution of it altogether; and
this accordingly took place.
The Danes received the first idea of forming estab-
lishments in India, from a Dutchman, who, discon-
tented with his own government, offered his services to
Christian IV. to form a settlement at Ceylon. This
man, however, dying on his passage, and the Danes
having been unfavourably received at Ceylon, they pro-
ceeded thence to the coast of Coromandel, where the
king of Tanjore allowed them to form a settlement at
Tranquebar. The little that remains to be told of this
Danish settlement will be found under our account of
the British proceedings in India.

Queen Elizabeth was the first English Sovereign who
thought of obtaining for her subjects a share in the trade
to India. In the year 1588, she granted letters to two
adventurers for the princes of India, and in 1596, other
letters. All these adventurers proceeded to the court
of the Great Mogul, by land, where they were well
received. The attempts to discover a passage by the
North from England to China having failed, the English
resolved to go round the Cape of Good Hope. Accord-
ingly the Queen, on the last day of the year 1600, granted let-
ters patent to a society of merchants in London to trade
to the East Indies. The object of the company was
principally pepper and other spices; and therefore their
voyages were to Achen, Java, and the Spice islands.
In the year 1612, four ships were sent out by King James,
for the purpose of conciliating the Mogul emperor,
some of whose vessels had been annoyed by the Eng-
lish in the Red Sea. The commander of this fleet suc-
ceded in his mission; and, at the same time, he ob-
tained from the court of Delhi the liberty of establish-
ing a factory at Surat; and this city was some time aft-
erswards regarded as the principal English station in
the west of India. The Portuguese, alarmed at the
success of the English, attacked their fleet near Surat,
but they were repulsed. This voyage, therefore, may
in some respect be regarded as the origin of the power
of the British in the East; the two foundations of which
were, the grant of the Mogul sovereign, and their own
naval ability and resources. The presidency of Surat
controlled all the factories in what may be called west-
ern India, or the tract extending from the parallel of
Cape Comorin westwards to the Persian and Arabian
Gulfs. Soon afterwards, they obtained an establish-
ment on the coast of Coromandel, at Masulipatam. To
this they were prompten, because the cloths of Coro-
mandel were in high request in the Spice Islands, and
consequently constituted the best medium of exchange
for pepper and other spices. In the year 1615, Sir
Thomas Roe was sent by King James as the first Brit-
ish ambassador to the Mogul, from whom he obtained
considerable privileges for the East India Company.
About the same time, the Zanzorin of Calicut granted
them similar privileges; so that a long range of settle-
ments was formed, immediately subject to the presi-
dency of Surat, among which were in the Mogul ter-
tory, Broach, Brodera, Ahmedabad, and Ajmeer; and
in the Zanzorin country, Craganpore and Calicet.

The disputes and wars with the Dutch followed soon
afterwards; and these were not only fatal to the British
settlements in Amboyna, but also prejudicial to those
settlements on the Coromandel coast. In consequence
of the war with the Dutch and the king of Gol-
dor, the Dutch, in return for the Dutch forts they
were attacked in the year 1620, they left this place, and,fixed them-
selves at Armeegum; but soon afterwards they again
took possession of Masulipatam. About 1640, the
Dutch began systematically to harass the European
commerce on the coast of Malabar. In consequence
of this, the English fixed on Madraspattam, which they
obtained from the chief of the district. They immedi-
ately built a fort, with the name of Fort St George; and in
1653, this station was raised by the Company to the rank of a presidency.

Nearly about the same time, the commercial trans-
actions of the British commenced on the Ganges. In
1634, they obtained from the court of Delhi the privi-
lege of a free resort to the port of Pipely, in the pro-
vince of Bengal. This privilege was much extended in
1645, chiefly through the professional skill and suc-
cess of a surgeon of one of the Company's ships, who
had thus, at the Mogul court, conciliated the favour
of the monarch. Factories were accordingly established
in Bengal, the principal of them at Hooghly; but this,
as well as the others, was subject to the presidency of
Madras, or Fort St George. The factories of the Brit-
ish at this time were Madras with its dependencies
Masulipatam, Madapolam, Pettipoul, and Hooghly; and
the factories subordinate to Hooghly, were Cossimbazar,
Balasore, Patna, and Malda.

But the Mogul government, as well as the other In-
dian princes, though they granted to the British the
privileges of commerce, yet denied them the exercise
of civil jurisdiction, or the use of military strength.
The factory of Surat was strongly built; but it was
not allowed to be either fortified or garrisoned. This
factory was exposed to still further inconvenience and
danger; for it was exactly placed on the debatable
ground between the Mogul and the Maharrattas, and,
as we have already seen, was more than once plundered
by Sevajee the Maharratt chief. It is probable, there-
fore, that the British would have been obliged to have
given up Surat, had not they gained an unexpected re-

History of Madras,
A. D. 1633.

Their facts-
ries in Ben-
egal esta-
lished.
The settlement of Madras was also exposed to great difficulties and danger. About the year 1636, the territory on which it stood, and which belonged to the king of Bussamur, was conquered by Meer Jumla, the general of the king of Golconda, who afterwards distinguished himself, as we have already noticed, as the ablest officer in the service of Arengzebe. This event, however, in the end proved fortunate to Madras; for in the years 1674 and 1676, the king of Golconda permitted the Madras government to build ships in any part of his dominions, and forbade his officers to molest the British commerce.

The settlements of Bengal also flourished; but in the mean time, the war between the emperor and the Mahrattas weighed heavily on the factories of Surat and Bombay. Sir John Child was at this period, what would now be styled governor general of the British settlements in India, while his brother Sir Jonah was leading member of the Court of Committees; their policy was, first the enlargement of the authority of the Company over such British subjects as were within the limits of their charter; and secondly, retaliation by force of arms on the Indian princes who had oppressed their settlements, and the attainment of political strength and dominion in the East. Hence it is evident that they laid the foundation of that system of aggrandizement, on which the British have ever since acted in India. In Bengal the design was to gain possession of the city and territory of Chittagong; but hostilities were prematurely commenced, and the attempt failed. On the side of Surat considerable advantage was at first gained by the capture of a number of Moonish vessels, richly freighted. But these enterprises, which had been undertaken while Arengzebe and the Mahrattas were nearly equally poised in strength and success, in the hopes that the latter would co-operate with the British, were brought to a premature conclusion by the overwhelming victories of Arengzebe. Sir John Child therefore applied to the Mogul for peace, which was granted in February 1690.

Almost immediately after the conclusion of the Mogul war, a new settlement of importance was acquired on the coast of Coromandel; that of Tignipatam, which was at first called by the Rajah of Ginger, and afterwards, when his territory was conquered by Arengzebe, the grant was confirmed by that monarch. The British fortified the station, and it has since been known by the name of Fort St David.

About the same time, a more important acquisition was made in Bengal. During the late hostilities in that province, the agent and council had retired to a town a few miles lower down the river, called Chuttanutte, immediately contiguous to which is that of Calcutta; as soon as peace was made with the court of Delhi, the agency was transferred to this latter place. At first, however, they could not gain permission to fortify it; but some of the rajahs, having rebelled against the Mogul monarch, the British, under pretence of being afraid that Calcutta would be attacked, obtained the walls round it. In 1698, Prince Azim, one of the grandsons of Arengzebe, who commanded the Mogul army in Bengal, was bribed by the British to confer on them a grant of the three connected villages of Chuttafutte, Gourimpore, and Calcutta, together with the judiciary power over the inhabitants. Shortly afterwards, the fortifications of the new possessions being completed, received, in compliment to the kind of England, the name of Fort William; and about the same period, the agency of Bengal was elevated to the rank of a presidency. For some years the position, and relative constitution of the British presidencies, had fluctuated very much; but Bombay at last superseded Surat completely; and from the date of the building of Fort William, the established presidencies were those of Madras, Bombay, and Bengal.

Soon after the death of Arengzebe, the settlement of Bengal was much exposed to the depredations and extortions of Jaffier, who had become nabob of that province. Warse, at length, of the insults and the inroads which they sustained, the Presidency of Calcutta, in the year 1719, sent an embassy, accompanied by presents, to the court of Delhi. It would, however, have failed altogether, but for the concurrence of two propitious circumstances. The one was, a cure effected on the emperor by Mr Hamilton, the surgeon of the embassy. This gentleman being offered any reward he chose, besought the grant of the Company's requests, which were instantly complied with; and the emperor, besides other valuable presents, gave him models of all his surgical instruments in pure gold. The other circumstance was, the retirement of the English from Surat, from which place the emperor had been long anxious to induce or force them to depart. Of the privileges granted to the Company, those relating to Bengal were the most important; and, indeed, they were long considered as constituting the great charter of the English in India. They were, that, in Bengal, all persons indebted to the Company should be delivered up; that English goods might be conveyed duty free through the Bengal provinces; and that the English should be at liberty to purchase the lordships of thirty seven towns contiguous to Calcutta. This last privilege, however, was never in fact granted, and even some of the others were rendered ineffectual; as, however, the privilege of exemption from duty, and a free passage for their goods was actually given, the English soon became the principal carriers from the province of the Ganges, and the shipping possessed by private Europeans in Calcutta, in ten years after the embassy, amounted to 10,800 tons.

From this time till the breaking out, in the year 1715, of the war between France and England, the English settlements in India present nothing deserving of particular notice or record. At the breaking out of this war, the English possessed the following settlements:—Bombay; Dabul, about 40 leagues farther to the south, in the province of Coemar; Carwar, in the province of North Canara; Tellicherry, on the sea coast of the Malabar province; Anjengo, their most southerly settlement on the western coast of the peninsula, on the sea coast of Travancore; Fort St David; Madras; Visigapatam and Balasore, on the Coromandel coast; and Calcutta. The principal French settlements were Pondicherry and Chandernagore; the latter about 20 miles above Calcutta, the former on the sea coast of the Carnatic.

In the year 1716, Madras was besieged by a French A.D. 1716., armament, and compelled to capitulate; but it was restored to the English by the peace of Aix la Chapelle. About the same time, the nabob of the Carnatic, within whose jurisdiction both Madras and Pondicherry were situated, and who successively took part with the combatants on both sides, sustained a total defeat from the Carnatic, a very inferior number of French. The event is memorable chiefly, as being the first which decidedly proved
the superiority of the European troops over those of Hindostan.

The territory of the Carnatic was one of the subordinate principalities immediately governed by nabobs, but subject to the soubhadar of the Decan, who was still regarded as a feudal prince under the Mogul emperor. Nizam ul Mulk, already frequently mentioned, who was soubhadar of the Decan, died in the year 1748, and the province was disputed between his son Nazir, and his grandson Murzaah. At the same time, the nabob of the Carnatic, Anwaraadeen, had been regularly established in that office by the Nizam, was opposed by Chunda Saheb; the latter and Murzaah made common cause, and to their alliance acceded M. D. de Langle, governor of Pondicherry, a man of great talents, intrigue, and ambition. The combined troops of the French and the two princes overthrew those of Anwaraadeen, on the frontiers of his own country, in a pitched battle, in which he himself was killed, and his eldest son taken prisoner, while his second, Mahomed Ali, escaped, and implored the assistance of the English. For some time the English hesitated, till at length they were induced by several reasons—the strongest, probably, a desire to curb and oppose the French—to espouse the alliance of Nazir and Mahomed Ali, who had made common cause. Such was the origin of the war for the succession of the Carnatic, or the Carnatic war as it is called, between the English and the French. In its progress, this war preserved essentially the character under which it had commenced, that is, in reality a contest between the English and French for superiority of power and extension of dominions in Hindostan. The violent deaths of Nazir Jung and his nephew introduced new competitors for the soubhadhip of the Decan; but the English, throughout the contest persevered in their object, of securing the nabobship of the Carnatic to Mahomed Ali. It was during this war that Mr Clive, afterwards Lord Clive, first appeared as a military character, and by his talents the English gained considerable success. In 1751, he defeated his opponents in the plains of Arani; and this victory was followed by the reduction of the forts of Timery, Conganzam, and Arani. These successes, however, were only against the Indian troops of Chunda Saheb; but, in the beginning of the year 1752, he attacked, and, after an obstinate battle, he defeated, near Arcot, an army consisting of 1500 sepoys, 1700 horse, with 150 French, and eight pieces of cannon. Soon after this, Chunda Saheb having been surrounded and cut off from his supplies by an English force, fled, but was taken and beheaded by his rival. After his flight, his army was defeated and routed by Major Lawrence, who had succeeded Mr Clive in the command of the army. The French immediately proclaimed Raja Saheb, his son, nabob of the Carnatic. Thus the forces of the English and French were engaged in regular hostilities against each other in India, at a time when no war existed between them in Europe. As soon, however, as intelligence of these events reached the courts of Versailles and St James’s, orders were sent out to put an end to the war; and a treaty was entered into, by which the French and English were to possess an equal dominion, military force, and commerce, on the east coast of the peninsula.

The breaking out of the seven years war in 1756, prevented the execution of this treaty, and rendered the French and English principals in the contest; the former captured the subordinate factories of their rivals, and at length even laid siege, though unsuccessfully, to Madras. The constancy, however, of the English, aided by the arrival of reinforcements from Europe, succeeded in turning the fortune of the war; the French were repeatedly defeated; Pondicherry was taken; and Mahomed Ali established in his principality. Salabut Jung, the third son of the Nizam, who had been raised to the musnud of his father by the assistance of the French, at length sought and obtained an accommodation with the English, in return for which they received from him a grant of the possessions which their victories over the French had given them, viz. the Circars of Masulipatam and its districts, and the Circar of Nizampatam. At the same time, they received from Mahomed Ali a part of the territory about Madras, and the advantage of a powerful influence in the Carnatic.

Before, however, the war in this part of India, of which our limits have obliged us to give this rapid and brief sketch, was thus happily terminated, the English were obliged to detach a force to the succour of their interests in Bengal. The causes and circumstances of their misfortunes there, it may be proper to trace with all possible brevity.

In the year 1741, Alivedi, as we have already seen, usurped the nabobship of Bengal. He died in 1756, leaving for his successor Surajah Dowla. This prince was strongly prepossessed against the English. Understanding that the governor of Calcutta was building a wall and digging a moat round that city, he took the alarm, and at last marched at the head of his army to attack it, with its dependent settlements. The town was gallantly, though not very skilfully, defended for three days, but then was obliged to surrender. Surajah Dowla had promised the prisoners their lives, but on the same night in which he entered the place, he ordered the massacre, (for it deserves no other appellation), which has rendered proverbial the black hole of Calcutta. The Europeans, to the number of 146 persons, were, in the most sultry season even of the Bengal year, confined for twelve hours within a cube of 18 feet, having no outlets except two small windows, strongly barred. All perished except twenty-three; and some of these afterwards experienced from the nabob fresh cruelties. As soon as intelligence of these events reached the English on the coast, they detached to Bengal 900 Europeans, and 1500 sepoys, under the command of Colonel Clive. In a few days after their arrival before Calcutta, the city was retaken, and the nabob being attacked in his camp, acquiesced in a pacification highly honourable and advantageous to the English. On him little reliance could be placed, especially as by the breaking out of the war between the English and French, he might naturally expect the assistance of the latter, who had, at their settlement of Chandenagore, contiguous to Calcutta, a force of 500 Europeans, and 300 sepoys. Under these circumstances, Colonel Clive resolved to attack the French settlement, which he accordingly did, with success. Still, however, the nabob was justly suspected; and as it was soon afterwards proved that he was in correspondence with the French, the English listened to the overtures of the discontented princes at his court, and at length resolved to support Meer Jaffier in his pretensions to the nabobship. This arrangement led immediately to the famous battle of Plassey, by the issue of which Meer Jaffier gained the nabobship, and his English allies a large treasure, a portion of territory adjoining to Calcutta, and a considerable influence with the new nabob. The British forces engaged in
History.

The nabob, derided by the British, A.D. 1760.

Treaty between the English and nabob.

By the treaty between the English and the new nabob, the latter agreed to pay a large sum into the treasury of Calcutta; and the English guaranteed his dominions. Jaffier, however, after he had acquired his power, seems to have been unwilling to pay the stipulated sum; and on being pressed by Colonel Clive to fulfil his engagement, he meditated the reduction of the British influence. This, and the non-payment of the money, were sufficient pretexts for stripping him of his newly acquired dominions; and to this object the British directed their plans, so as to accomplish it with the least appearance of injustice.

Before, however, we narrate these plans, it will be proper to attend to the affairs of India in another quarter. In the year 1759, the son and heir apparent of the Mogul appeared in a hostile position on the frontier of the provinces he had already ravaged, and towards invaded Barhar with a view of possessing himself of the suzerainty of Meer Jaffier. As the English were bound to support him, Clive, who was now governor of Bengal, joined his army to that of the nabob’s, and the allies drove the enemy beyond the Ganges. In the same year, and soon after the close of this campaign, the Dutch projected the overthrow of the English establishments and influence in Bengal. An expedition for that purpose was fitted out at Batavia, which in the month of August entered the river of Bengal, with the profession of proceeding to the Dutch settlement at Chinsurah. As Clive was apprehensive that the nabob might take advantage of this circumstance, he resolved to call upon that prince to insist on the departure of the Dutch, as they were within his territories. This, however, he did not do; and the Dutch landed their whole force near Calcutta. In this emergency, Clive was at a loss in what manner to act; for the English and Dutch were at peace. As, however, some decisive steps were necessary, he ordered Colonel Ford to intercept the march of the Dutch; this was accordingly done with most complete success.

A.D. 1760.

In February 1760, Colonel Clive left Bengal for England; and about the same time, the dominions of the nabob were again menaced with invasion from the interior. A Maratha army entered the district of Burdwan, and Shah Alum reappeared on the frontier of Berar. Against the former, the nabob in person led an army, partly composed of British troops, but the campaign in this quarter proved unsuccessful. The Mogul was opposed by a British army, commanded by a British officer, but the operations of the latter were much impeded by the obstinacy of the nabob’s son, who commanded an auxiliary force, so that the Mogul, though defeated near Patna, escaped into the southwest districts of Bengal, where he effected a junction with the Marhatta general who had invaded Burdwan. He was soon, however, compelled to retreat into Berar. This campaign, which presented nothing else remarkable, was closed in July, by the setting in of the rains, and the death of the young nabob, who was struck dead with lightning in his tent.

By this time, the plans of the British against Meer Jaffier were complete; accusations of various kinds, besides the non-payment of the money, were brought against him; and in September 1760, a treaty was privately made at Calcutta between the British and Meer Cossim, son-in-law and general of the nabob. By this treaty it was stipulated that Cossim, under the title of dewan or deputy to the nabob, should obtain the real possession of the nabobship, and that he should grant to the English, for the pay of the army, the districts of Burdwan, Midnapore, and Chittagong. It is also said that he promised the projector of this revolution two millions of rupees; this, however, was expressly denied in the examination before the Select Committee of the House of Commons. Meer Jaffier was soon afterwards brought to Calcutta, and thus deprived even of the name and appearance of power.

Meer Cossim had not been long possessed of the nabobship, when he entered into projects unfavourable to the English; levying high duties on their merchandise contrary to treaty; and at last massacring the English deputies who were sent to him to adjust matters. The English, therefore, in order to punish him, resolved to restore Meer Jaffier to the dignity from which he had been degraded. As a condition of his re-instatement, he consented to cede to them the districts already granted them by Cossim, of Burdwan, Midnapore, and Chittagong, and also to grant them those commercial privileges which Cossim had withheld. On the 7th of June 1763, he was proclaimed soubhadar of the three provinces; and the British government also declared war against Cossim. On the 19th of July, of Cossim’s generals was totally defeated by a British force, half way between Calcutta and Moorshedabad, and on the 24th the latter place was taken. Advancing rapidly after these successes, on the 2d of August they encountered, on the plain of Garih, the whole of the hostile force at that time in the lower part of Bengal. It was composed of about 15,000 black cavalry, and 10,000 regularly disciplined sepoys, with 17 pieces of cannon, managed by 170 Europeans. After an obstinate contest of four hours, the enemy were completely routed. Cossim was himself in the province of Bahar, and thither the British pursued him. In the beginning of October they gained possession of Monghir, and in November of Patna, Cossim still fleeing from danger, having escaped into the dominions of the Nabob of Oude, carrying with him treasure and jewels to the value of two millions sterling.

The same year which witnessed the expulsion of Cossim from the three provinces, also produced, in Europe, a pacification between France and England. By the treaty of peace, France, whose recent acquisitions, as well as her ancient possessions in India, had been wrested from her, was restored to the factories of which she had been mistress in the year 1749, but she renounced any pretensions to the territories which she had recently acquired on the coast of Coromandel and Orissa, and engaged neither to erect fortifications, nor maintain troops in the souah of Bengal. Mahomed Ali was acknowledged lawful sovereign of the Carnatic. The English sacrificed but a small part of the territory which they had gained; they retained unimpaired their authority at the courts of the Carnatic and Bengal; they retained, in addition to their old settlements, the newly acquired possessions of the Circars of Masulipa-
tam, and its dependant districts, which they had conquered from the French; also the castle of Surat, the Jaghire, or territory round Madras, the Caleutta zemin- dary, and the districts of Burdwan, Midnapore, and Chittagong.

In the pursuit of Cosseim, the British army had reached the interim frontier of the territories of Bengal and Oude: the fugitive prince had taken refuge in the court of Sujah Dowla, otherwise called the Naib Vizier, which, at the same time, harboured a more illustrious exile, the young Mogul. The British camp now became the scene of complicated negociations; an alliance was proposed to Sujah Dowla, which he rejected. While these negociations were going on, discontents prevailed in the British army. Encouraged by this, Sujah Dowla, who had already collected an army on the frontiers of Oude, determined on hostility; and he was joined by the Rajah of Benares. In March 1764, Major Carnac took the command of the British forces, and having restored discipline and subordination, repulsed the vixier in an obstinate engagement near Patna. The war was now carried into the province of Oude, and Major Carnac was succeeded by Major Monro. On the 34th of October, was fought the celebrated battle of Buxar, on the river Carummas, about 100 miles above the city of Patna. The British army consisted of 850 Europeans, and 6215 sepoys; the combined troops of Sujah Dowla and Cosseim consisted of 40,000 men. After an arduous contest of three hours, the army of the vixier retired in disorder, leaving on the field 139 pieces of cannon, and blowing up some of their powder magazines; 2000 troops were slain on the field of battle. The loss of Major Monro's army was trifling. They were being only 87 Europeans and 712 sepoys. The flight of the allies was so rapid, that they did not stop at Buxar, but hastened to a small river beyond it. Over this was a bridge of boats, which, however, they had not all crossed, when Sujah Dowla directed the bridge to be destroyed. By this act of generalship he sacrificed indeed the rear division of his army, which, to the number of nearly 2000 men, were drowned; but he saved his main body from certain destruction, and at the same time preserved from capture the immense treasures of Cosseim as well as his own. A native historian describes the camp of the two chiefs in the following terms: "A bridge of boats being thrown over the Ganges, the allied armies began their march in numbers not to be reckoned; but, from the ignorance of the generals and want of discipline, murdering and plundering each other. It was not an army, but rather a moving nation." On the following day the Mogul, who had taken no part in the battle, sought and obtained the protection of the British, offering them terms highly favourable to their views and plans of aggrandizement and extent of territory.

Sujah Dowla was now obliged to struggle for his existence. He offered to negociate; but as he refused to deliver up Cosseim, his offer was rejected. At last having dismissed his ally, who took refuge in upper India, he voluntarily repaired to the British camp, and surrendered himself to the general. Terms were made with him, by which the entire territory of Oude, except the districts of Corah and Allahabad, were restored to him; the excepted districts were allotted to the Emperor, the fort of Allahabad being assigned for his residence. In return for these cessions, and for an annual stipend for his support, the Emperor, besides a confirmation of the territorial acquisitions which the British had made, either on the soubhadiar of Bengal, or on the coast, conferred on them two important favours: he invested them with the Deewance of the three provinces of Bengal, Bahar, and Orissa; the second grant was that of the five northern circars. Over these districts indeed he had only a nominal claim, derived from the former Mogul conquest, in the latter days of the Mogul government. At this time, they belonged to the soubhadiar of the Deccan. In 1754, he had granted them to the French, then his allies, and on their being defeated by the English, the circars reverted to him. After the general peace of 1763, the French again endeavoured to gain a footing in them; and this induced Lord Clive, who arrived in India for the second time, in 1765, to obtain from the Mogul the proprietary grant of this territory. In the year 1766, four of the circars were given up by the soubhadiar; the fifth, held by a brother of the Nizam, was granted in reversion to the British. In return for these cessions, the British promised the soubhadiar the assistance of their troops, whenever he might need it, to settle the affairs of his government. About the end of the year 1766, having united himself with a Mahratta chief against Hyder Ali, sovereign of the Mysore, he applied for these troops, which were granted him, even before his object or that of the Mahrattas was known. As soon as the British troops had joined, the united army entered the territory of Mysore.

It was on this occasion that Hyder Ali first displayed those talents which afterwards rendered him so very formidable. He fought off the Mahrattas by large bribes. Next he entered into negociations with the Nizam with such effect, that in August 1767, the armies of the Nizam and Hyder actually united at Bangalore, from which place they made irregular incursions into the Carnatic. Had Hyder adhered to his own plan of the campaign, which was to elude a general action, and to harass the British by his superiority in cavalry, the latter must have suffered dreadfully; but on being accused of dilatoriness by the Nizam he consented to change his plans. The result was fatal to his interests and views; for by a succession of obstinate engagements and bloody defeats, the allied army was driven out of the Carnatic. The Nizam deserted Hyder in his misfortunes, made peace with the Madras government, and retired to his own dominions. This defection, though it weakened Hyder, gave him greater liberty of action, which he improved to the utmost; and partly by the nature of the country which was the scene of warfare, and partly by the mode in which he conducted the campaign, he baffled the British for a considerable length of time. The intelligence of his being able to oppose an enemy hitherto invincible by the Indian princes, so raised his reputation, that adventurers flocked to him from all parts, and his cavalry were soon increased to upwards of 90,000. At last he was induced to give up his plan of defensive and dilatory warfare, in order to protect a fort besieged by the British. The consequence was an obstinate engagement, in which, notwithstanding his vast superiority, he was defeated. He still persevered, however; and in January 1769, having recovered his own provinces, marched into the Carnatic, which he ravaged with fire and sword. At this period the British were commanded by General Smith, who, by a dexterous movement, cut off the enemy from his own country. From the difficulties, however, which seemed entangling him, Hyder was extricated by his own spirit of enterprise; for having, by a variety of movements, contrived and executed with great skill and adroitness, drawn the British forces to a considerable distance from Madras, he directed his
and appears before Madras.

War between the Maharrattas.

In 1773, the Maharrattas crossed the Ganges to invade the Itihilla country; a brigade of the British army marched to the western frontier of that country, and drove the enemy beyond the river. For this protection, the Itihilla chiefs had stipulated to pay Sujah Dowlah, as whose allies the British acted, 40 lacks of rupees; but when the service was performed, the payment was evaded. This breach of treaty led to the invasion and conquest of the Itihilla country in 1774. A considerable tract of land in the Doab was also conquered from the Ghaouts. Thus the boundary of the province of Oude was advanced westward within 20 miles of Agra; northward to the upper part of the navigable course of the Ganges; and southwestward to the Jumna river. In the following year, on the death of Sujah Dowlah, the province of Benares was ceded to the British.

In the year 1778, a war broke out between the British and the western Maharrattas. This occasioned the march of a brigade from Bengal across the continent to the side of Bombay and Surat. By some misunderstanding, it was obliged to capitulate with the Maharrattas, general on the 9th of January 1779. One of the terms was, that a body of troops, which were advancing on the other side, should be obliged to return to Bengal; but this condition was not complied with, and the expedition proceeded. There were not more than 7000 men, all native troops, commanded by European officers; and yet they marched from the banks of the Jumna to the western sea in despite of the Maharrattas, whose empire they traversed almost the whole way. This war was attended by the conquest, by the English, of the finest parts of the Guzerat and the Concan, including the important fortresses of Bassag and Amedabad; in short, of the whole country from Ahmedabad to the river Pennar, and inland to the foot of the Ghauts; and on the side of Oude, the province of Gobra and other districts, together with the celebrated fortress of Gwalar, were reduced, and the war was carried into the heart of Malwah. But, in consequence of the war which broke out in the year 1780 with Hyder Ali, peace was made with the Maharrattas, after detaching Scindiah, the principal member of that state, from the confederacy. All the acquisitions made during the war were given up, except Salsette and the small islands situated within a gulf formed by Bombay, Salsette, and the continent.

Hyder Ali, indignant at the refusal of the British to assist him against the Maharrattas, made peace with them, and prepared for the invasion of the Carnatic. On the 24th of July 1780, Hyder Ali's cavalry were only nine miles distant from Madras; and it was ascertained, that his whole force consisted of 100,000 men, among whom was a large body of European troops, under French officers, and commanded by Colonel Lalley. In this emergency, Sir Hector Munro ordered the British army to assemble at Conjeeveram, and directed Colonel Baillie, who commanded a detachment at Gumerpatna, to join him at that place; but this detachment was cut to pieces by Tippoo Saib, Hyder's son. This obliged the Carnatic army to retreat, till Sir Eyre Coote arrived from Bengal with a brigade of 7000 men, and assumed the command. Sir Eyre immediately restored the spirits of the army, and in a very short space of time defeated Hyder in five several battles. In some instances, however, the British were not so successful; for Tippoo entirely defeated a detachment of about 2000 infantry, and 300 cavalry, under Colonel Braithwaite. In the end of the year 1782, Hyder died; and one of the first objects of Tippoo, who succeeded him, was to recover Canara, which had been conquered by a detachment under General Matthews. It had been supposed by the presidency of Bengal, that an attack on Tippoo's provinces on the west of India, would, by giving an easy and immediate entry into the most valuable part of his dominions, draw him off from the Carnatic, which he still occupied, notwithstanding the defeats which his father had sustained. Accordingly General Matthews was sent into Canara, a province which Hyder Ali had conquered in 1763, and he succeeded in reducing the whole of it. The scheme succeeded in drawing Tippoo from the Carnatic into Canara; but at the dreadful expense of the loss of General Matthews and his army, which was obliged to capitulate, on condition of being allowed to go to Bombay. This condition, however, was not fulfilled; and General Matthews, and 20 of his officers, were poisoned, and most of his troops were massacred. At last Tippoo finding that the Maharrattas, his invertebrate enemies, were at peace with the English, and at liberty to attack him, and being deserted by the French in consequence of the peace of 1783, condescended to treat in March 1784. By this treaty, matters were restored nearly to the condition in which they had been before the commencement of hostilities.

Having given this brief sketch of the wars in which the British were engaged with the Maharrattas, and with Hyder Ali and his son, it will be proper to advert to a general confederacy which seems to have been entered into against the British, of the plan of which these wars formed a part. The Nizam of the Deccan having taken disgust at the conduct of the Madras government towards him in 1779, determined on revenge. Under the influence of this feeling, he resolved to engage all the principal powers of Hindostan Proper and the Deccan against the British. The Poonah Maharrattas were already engaged, and Hyder was preparing. There remained the Nizam himself, and the Barar Maharrattas. Each party was to pursue a particular scheme of attack, suited to its local position and means. Hyder was to attack the Carnatic; the Nizam the Circars; the Poonah Maharrattas were to keep the Guzerat army employed; and the Barar Maharrattas were to invade and lay waste the provinces of Bengal and Bahar. But this confederacy, like most others among nations of different habits and interests, did not act in concert, or towards the attainment of a common object: each member of it pursued its own peculiar plans and interests. The
operations of Hyder Ali and of the Poonah Maharattas have been already detailed; the army of the Berar Maharattas, though it was put in motion, never arrived at the projected scene of action, and the Nizam speedily made peace.

Before we proceed to narrate the particulars of those wars which took place between 1784 and the present time, we shall, as shortly as possible, give an account of the divisions of Hindostan, as they existed in that year, when the British were at peace with all the Indian princes.

In 1784, the British possessed, in full sovereignty, the whole souibah of Bengal, and the greatest part of Oude. In Orissa they possessed the districts of Midnapore; the district of Benares also belonged to them. Of the five northern circars, four were in their possession, and these occupied the sea coast from the lake of Chilka to the northern banks of the Krishna river. Their territories in the Carnatic were confined chiefly to the tract called the Jaghire, which extends along the coast about 108 miles, and stretches inland 47 miles in the widest part. They also were masters of Bombay and Salsette. The dominions of the nabob of Oude lay on both sides of the Ganges, occupying nearly all the flat country between that river and the northern mountains, as well as the principal part of the Doob, or the tract of land formed by the approximation of the Ganges and Jumnah, to within 40 miles of the city of Delhi. The district of Rampoor, at the foot of the northern mountains, was held by a Rohilla chief. The Seiks occupied the most western part of Hindostan, viz. the whole province of Lahore, the principal part of Multan, and the western part of Delhi. There were besides several petty princes in this part of Hindostan.

The Maharattas formed two distinct states; that of Poonah, or the western; and that of Berar, or the eastern. These states occupied all the southern parts of Hindostan proper, together with a large portion of the Decan, from the confines of Agra northward, to the Krishnah southward, and from sea to sea across the widest part of the peninsula; comprehending Malwah, Orissa, Khandesh, and Bejapour; the principal parts of Berar, Guzerat, and Ajmeer; and a small part of Dowlatabad, Agra, and Allahabad. The western state was divided among a number of chiefs, who professed obedience to the Paishwah, or head. The Paishwah resided at Poonah, and there were three principal chieftaigns on the north of this city, and two on the south. Those on the north were Scindiah, Holkar, and Futtysing. The first was indeed a sovereign prince. After the Maharattas peace, he extended his frontier from Malwah towards the Jumnah; carried his arms northward to Delhi, and obtained possession of the person of the Great Mogul. The principal part of Berar was held by the Nagoor Rajah, and the remainder by the Nizam of the Decan. There were several states tributary to the Maharattas; among others, the Rajpoot principalities of the souibah of Ajmeer.

The possessions of the Nizam comprised the province of Golconda; the principal part of Dowlatabad; the western part of Berar; and Guntoor, one of the five northern circars. The dominions of Mahomed Ali, nabob of the Carnatic, commenced on the south of the Guntour circar, and extended along the whole coast of Coromandel to Cape Comorin. The dominions of Tippoo Sultan comprehended generally the provinces of Mysore, Bednore, Coimbatore, Canara, and Dindigul, besides his father’s conquests to the north; stretching as far as Travancore and Madura on the south; Coonda and Bejapour to the north; Guntoor and Ongole on the north-east, and the sea on the west. Tippoo was without doubt the most powerful of all the princes of Hindostan. His dominions were equal in extent to Great Britain; his revenue was computed at four millions Sterling; and his military establishment consisted of 72,830 regulars; 49,000 in garrison; 7000 irregulars, and 26,300 auxiliaries; in all, 155,130 men. Of the regular troops, 27,400 were cavalry; 36,000 sepoys infantry, Hindoos and Mahomedans; 7900 topsasses or hatmen, that is, the descendants of the Portuguese and other Europeans, infantry; 800 European cavalry; and 540 European foot. The artillery corps, consisting of European topsasses, &c. amounted to 1950. There were 110 guns attached to the battalions; the horse garrisons on the frontiers amounted to 21,000, and the foot garrisons to 28,600. The auxiliaries were supplied from the raahs of Hydroug, Darwar, &c. and consisted of 13,300 horse, and 13,000 ponee, or irregular troops.

It was not to be supposed that a person, possessed of the ambitious and restless disposition which characterised Tippoo, would long remain at peace with such an immense force at his disposal, or that he would find any difficulty in raising pretences for commencing hostilities. Accordingly, towards the end of the year 1789, he approached the country of Travancore for the avowed purpose of recovering two places which the rajah of that district had purchased from the Dutch, but which Tippoo alleged were dependent upon him, as forming part of the possessions of his tributary the Rajah of Cochin. On the 29th of December, he stormed the lines of the Rajah of Travancore, who was not disposed to accede to his demands; but without success. As this Rajah had put himself under the protection of the British government, and was acknowledged to be so, by the treaty concluded with Tippoo in 1784, war between the latter and the British seemed unavoidable. Lord Cornwallis at this time was Governor General of India. His first object was to enter into a treaty offensive and defensive with the Nizam. This was accordingly concluded on the 4th of July 1790. A treaty was also formed with the Paishwah of the Maharattas. The provisions of these treaties were, that measures should be instantly taken to punish Tippoo, and to deprive him of the means of disturbing the general tranquillity, and that the Nizam and the Paishwah should both vigorously prosecute the war.

The British Madras army was assembled on the plain of Trichinopoly, and on the 24th of May 1790, General Meadows, who was to take the command, joined it. On the 12th of June, he entered the territories of the Sultan. His first object was to relieve the Rajah of Travancore; and, before the end of the year, he was completely successful. In the mean time, the Bombay troops under general Abercrombie conquered the valuable districts below the Ghaunts on the west and the north, as far as the River Baliaapatam. The next campaign was carried on by Lord Cornwallis himself in the centre of Tippoo’s kingdom. The important fortress of Bangalore was conquered. A successful battle was fought near Seringapatam; but the unfavourable season of the year, which now began, and the delay of the Maharattas, prevented his Lordship from attacking that city, which had been his principal design when he commenced the campaign. In the mean time, the Bombay army was marching to join his Lordship; but being unable to effect the junction, from the badness
of the roads, and the swelling of the rivers, they were compelled to retrace their steps over those mountains which formed an almost impassable barrier between Mysore and the Malabar coast. In this march and retreat, the troops suffered dreadfully; but the sufferings were mild compared to those which the Madras army underwent while obliged to remain inactive in the heart of Tippoo’s dominions on account of the rains. They were infected with an epidemic disease, the ravages of which were greatly increased by a scarcity of provisions; and, to add to these calamities, the small-pox raged in the camp. Fortunately, they were soon joined by the allied force of the Mahrattas, amounting to 32,000 cavalry; and soon afterwards, the troops of the Nizam joined them; but from neither of these allies could Lord Cornwallis expect much efficient assistance, especially in the moment of danger, as their equipment and discipline were excessively defective. In the month of June 1791, his Lordship set out towards Bangalore. His first object was to secure an easy and regular communication between the Mysore and Ceylon, as from the latter the supplies of the army were chiefly to be drawn; but this communication would be impracticable, so long as the various hill forts which commanded the passes were in the possession of Tippoo. They were uncommonly strong, both by nature and art. Of these, Savendroog, Chittedroog, and Kistnaugury, were the most remarkable for natural strength. The first is surrounded by a forest of natural wood, or jungle, several miles in depth, thickened with clumps of planted bamboo to render it as impenetrable as possible. It is impossible to invest or blockade it closely; the rock forming a base of 8 or 10 miles in circumference, which, with the jungle and lesser hills that surround it, includes a circle of 20 miles. From this base, it is reckoned to rise above a half a mile in perpendicular height. This huge mountain is further rendered strong by being divided above by a chasm that separates the upper part into two hills, each, with their defences, forming two citadels, and capable of being maintained independent of the lower works. This stupendous fortress, so difficult of approach, is no less remarkable for its noxious atmosphere, occasioned by the surrounding hills and woods, than for its wonderful size and strength.

The right wing of the main army, under the command of Lieutenant Colonel Stewart, was ordered to the siege of this tremendous fortress. In three days a practicable breach was effected, and the troops advanced to the storm, Lord Cornwallis in person superintending the attack. On the appearance of the Europeans advancing, the garrison were seized with panic and fled, and the breach was carried without meeting or even overtaking the enemy. The main body endeavoured to gain the western hill, and if they had done so, the siege must have recommenced; but they were closely pursued by a small party of the British who entered the different barriers along with them, and gained possession of the top of the mountain. Thus, in less than an hour, in open day, this fortress, hitherto deemed impregnable, was stormed without the loss of a man, only one private soldier having been wounded in the assault. Other fortresses were also taken, so that the convays reached the army without the least delay or opposition.

On the 28th of January 1792, the Bombay army, having passed the Ghat, joined Lord Cornwallis. They consisted of 8400 men, and as soon as the armies of the Mahrattas and of the Nizam had also joined, Lord Cornwallis made preparations for besieging Seringapatam. On the 5th of February, the city was seen by the whole army from the heights which they had mounted, lying six miles to the north-east of it. The sultan’s army was encamped under the walls of his capital. Seringapatam is placed at the upper end of an island surrounded by the Cavury, which is here a large and rapid river, having a very extensive channel, impeded by rocks and fragments of granite. The fort occupies about a mile at the west end of the island, and is an immense and unfinished building. In fortifying the town, Tippoo retained the long strait walls and square bastions of the Hindoos, and his glass was in many places so high and steep as to shelter the assailants.

The camp of the allies was pitched on the north side of the island. The British formed the front line, the reserve was placed a mile in the rear, and the Nizam and Mahrattas were stationed still farther in the rear. Tippoo’s fortified camp was under the walls of Seringapatam, within a bound hedge strengthened by redoubts. In this line there were 100 pieces of artillery; and in the fort and island, which formed his second line, there were upwards of 300 pieces. The whole of his army amounted to 40,000 infantry, besides a large body of cavalry.

On the night of the 8th of February 1792, Lord Cornwallis resolved to attack Tippoo’s camp. For this service he selected 2500 Europeans, and 5900 native infantry, but without artillery. The attack was completely successful. It was made in three columns, and taken. The centre column under Lord Cornwallis, attacked the Sultan’s redoubts, and having carried it, forced their way into the town; and, by the other columns, the enemy’s positions on the north side of the river, and almost the whole of the island, were carried. Eighty guns were taken, and the loss of the Sultan in the battle is said to have been 4000; but the desertion was so great after the overthrow, that his army was reduced in number at least 20,000. The loss of the British was 585.

The British army having thus obtained possession of the island and town of Seringapatam, were immediately employed in making preparations for the siege of the fortress. But Tippoo, after several unsuccessful efforts to retrieve his losses, set length on the 24th of February agreed to terms of peace, by which he agreed to pay 3 crores and 30 lacks of rupees, about 31 millions sterling—so to relinquish half his dominions and—150,000 territorials for the due performance of the treaty. Lord Cornwallis gave up to the troops his whole share of the prize money, amounting to £47,244; and General Meadows, the next in command, his, amounting to £14,997.

On this occasion, the force brought against Tippoo was one of the most formidable ever seen in Hindostan. On the 16th of March 1792, the British army above the Ghauts amounted in all to 11,000 Europeans, 31,600 natives, and 190 pieces of cannon. The Mahrattas, the Nizam’s, the Rajah of Travancore, and the other auxiliary forces, amounted to about 40,000 men, of whom 30,000 were cavalry. Towards the conclusion of the siege, allowing four camp followers to every soldier, the total number of persons attached to the camp of the confederates exceeded 400,000.

After the termination of this war, the alliance between the British and the Nizam became more inti-
mate; but, on the other hand, a coolness arose between them and the Poonah Mahrattas, principally on account of the close connection between them and the Nizam. Scindiah was acknowledged an independent power by Lord Cornwallis, who did not think it proper to prevent that chief's ascendantment. The consequence was, the complete establishment of his power over the northern parts of Hindostan; the possession of the person of the Emperor of Delhi; the formation of a large and formidable corps of regular infantry, chiefly under French officers; the erection of foundaries and arsenals; and, in short, the accumulation of those vast military powers and resources, which enabled his immediate successor to carry on a war, at the same moment, in the Deccan and Hindostan, against the British government and its allies.

Lord Cornwallis had formed treaties with many of the Indian princes, the chief of whom were the Nabob of the Carnatic and the Vizier of Oude; with the former it was stipulated, that, in the event of a war in that part of India, the British should charge themselves with its conduct, on condition that the Nabob applied a certain proportion of his revenue to its support. If he failed in this condition, the British were vested by the treaty with a right to appoint superintendents and receivers in his territory; they were also to assume the management of the Carnatic, which was to remain in their possession during the continuance of hostilities. The treaty with the Vizier of Oude related principally to the regular payment of the sums which, by former treaties, he had engaged to pay to the British.

When the account of war between France and England reached India, Pondicherry was immediately attacked, and taken by an army from Fort St. George. In the month of August 1793, Lord Cornwallis sailed for England.

He was succeeded as governor-general by Sir John Shore, afterwards Lord Teignmouth. During his administration, no war with a foreign power occurred; but that period was marked by political changes in the state of India of great importance. A rupture took place between the Nizam and the Mahrattas: the former entertained the most friendly disposition towards the British government, whereas the latter viewed the success of our armies with alarm, and, consequently, could not regard the Nizam with any friendly feelings. They believed, that if they could reduce his power, they would not only increase their own, but injure the British government. As they trusted for the accomplishment of any object which they had in view, not more to their military strength than to intrigue, they had for some time gained over the Nizam's minister, who acted more at their command than at that of his master. As soon as the Nizam found this out, he put him to death. Immediately before the occurrence of hostilities between the Mahrattas and the Nizam, Tippoo, whose active spirit of hostility against the British had led him to commence intrigues with the French government, the court of Hyderabad, and the court of Poonah, almost at the same moment that the peace of Seringapatam was concluded, had assembled an army, and threatened to come forward as an ally of the Mahrattas against the Nizam, in the quarrel between those states. Sir John Shore seems to have been of opinion, that the British government was not bound, either by express treaty or by political expediency, to support its ally the Nizam, in the event of his being attacked by Tippoo, during the period when he was engaged in a war with the Mahrattas. This war, however, lasted such a short time, and Tippoo was so completely occupied in his own dominions, repairing the losses he had sustained, that he could not accomplish his object of attacking the Nizam.

The war between the Mahrattas and the Nizam began in February 1795; the advanced corps of the former, under the command of Dowlat Row Scindiah, marched towards the Nizam; and on the 11th of March attacked that prince, who had advanced from Bedar to meet him. After a general action, in which both parties were thrown into some confusion, and neither obtained any decided advantage, the Nizam, yielding to the fears of his women, who attended him in the action, retreated during the night of the 11th, and took shelter in the small fort of Kurdal. This fort is completely surrounded by hills, except in one direction, which the Mahrattas immediately occupied; and by that means hemmed in the Nizam's army, and cut it off from all supplies. After remaining for some weeks in this situation, he was obliged to conclude a peace, Treaty of Kurdal. The exact particulars of which are not known; but it is understood that he agreed to cede to his enemies a country, the annual revenue of which was about 35 lacks of rupees, including the fort and district of Dowlatabad, and to pay them three crores of rupees. After the convention was settled, the Nizam returned to his capital, and the Mahratta confederates towards their respective countries. Very shortly afterwards the young Paishwah died suddenly, and the eldest son of the Nizam rebelled against his father. The Nizam, alarmed at this, pressed the instant return of the English subsidiary force to Hyderabad, and took every step to manifest his attachment to the British government. The troops were immediately ordered to march; and they were already advancing to join the army acting against the son, when accounts were received of his defeat and capture.

At this period, the French, under M. Raymond, were employing every means in their power to ingratiate themselves with the Nizam; and, as they had acquired great reputation by the active part which they took in the reduction of his son, they succeeded in their object; and the influence they possessed they directed against the British.

The death of the young Paishwah contributed to restore to the Nizam a part of that power and rank among the states of India, which he had lost by the treaty of Kurdal, as it occasioned the most serious dissensions among the Mahratta chiefs, whose interests were deeply involved in the succession. The principal minister at Poonah was desirous of placing an infant on the Musnud to the exclusion of the legitimate heir. This plan was opposed by the agent of Dowlut Row Scindiah; and that chief prepared to march to Poonah to support the legitimate heir. Under these circumstances, the minister endeavoured to gain the support of the Nizam, and for this purpose he resigned all those great cessions which had been obtained from the Nizam by the convention of Kurdal. In the mean time, however, Dowlut Row Scindiah, having arrived at Poonah with a force, which gave him a decided superiority, and thus placed the legitimate heir, Badgeron, on the Musnud, a new negotiation was opened with the Nizam, not so favourable as that which he had just concluded; for by this, he agreed to cede one fourth of the territory, and to pay one fourth of the sum fixed by the convention of Kurdal. The success of Dowlut Row Scindiah in this important transaction, esta

Influence and power of Scindiah.
blished his influence and ascendancy in the Mahratta empire. This was greatly augmented by the death of Tuckoojee Holkar, most of whose possessions he usurped, after putting to death his eldest son, and imprisoning the other members of his family. He also obliged the Paisiahwad to cede to him the important fortress of Ahmadnagar and its surrounding district, by which he not only obtained the command of the city of Poonah, but the best passage into the territories, either of the Paisiahwad or the southward of the Deccan.

This great and rapid increase of power and influence, especially as it was supported by an army disciplined in a great measure after the European manner, by French officers, gave some uneasiness and alarm to the British government of India. Almost the whole of that part of Hindostan which had been subdued by Scindiah, as well as the establishment and realization of his claims upon the Rajpoot states, were entrusted to the management of the French general who commanded his infantry.

In 1798, a treaty was entered into by the British and Saadut Ali Khan, who had claims to the Munsad of Oude, which the British promised to support; in return for their assistance, he promised to vest in them the defence of his dominions, and to pay them 76 lacks of rupees; and in the event of the failure of any of these instalments, the British were to be put into possession of the country of Oude, of the value of ten lacks of rupees. Saadut Ali Khan also agreed to pay the amount of any expense which the British might incur in placing him on the throne, and to cede the fortress of Allahabad. There were several other articles highly favourable to the British, and which were evidently calculated to assist them in obtaining the entire sovereignty of the province at some future period. These were the principal transactions which happened in India during the government of Lord Teignmouth.

On the 24th of April 1798, Lord Wellesley reached India. Affairs at this time were rather critical for the British interest. The designs of Tippoo to renew the war were not undoubted; a French party prevailed at the courts of the Nizam and of Scindiah; the Poonah Mahrattas were entirely under the power of the latter; and the court of Berar was suspected to be adverse to the British, whom it had long looked upon with jealousy and apprehension. The territory of Oude was not yet quiet under the government of Saadut, who still called upon the British for support in the exercise of that power to which they had raised him. The Carnatic, also, over which Oumut Ul Omraah ruled, was in a weak state; and yet it was evident, that in the event of hostilities in that part of India, the British must rely greatly on the assistance of its nabob. The finances of the British government had been greatly exhausted by the expeditions against the Dutch possessions in Ceylon and the Spice Islands, and a considerable part of the army of Coromandel was likewise absent on those expeditions.

Lord Wellesley immediately began a system of measures and operations, which in his opinion would strengthen the British dominions in India, and secure them against any formidable attack by the native princes. In September 1798, a favourable treaty was concluded with the Nizam, by which, among other conditions, he promised to disband the French corps in his service, and to deliver over its officers to the British government, whenever the whole of the British force, to be stationed in his dominions, reached his capital. The British, on their part, agreed to arbitrate the points that were in dispute between him and the Poonah Mahrattas; and if these were not settled, to protect his dominions from any unjust demand made by them. That part of the treaty which related to the dismissal of the French army, was of difficult execution, but its length was accomplished by the firm and decisive measures of the British, aided by a mutiny, which at this time broke out in that army.

Lord Wellesley next endeavoured to bring Tippoo to reason; but his attempts failing of success, in the month of February 1799, he directed the British armies to advance against that prince, empowering, however, the commander in chief, General Harris, to treat with Tippoo if he shewed a sincere desire for peace.

The army under General Harris, after having been joined by that of the Nizam, entered the territories of Mysore, on the 3rd of March, unopposed by the Sultan; who had, as soon as he saw the preparations of the allies, hastened to attack the Bombay army under General Stewart, which was posted in Coorgah, and ready to co-operate in the reduction of Seringapatam. He was however repulsed in his attack on the Bombay army, with great loss. His next object was to impede the march of General Harris' army, which he met between Sultampet and Malavilly, on the 27th of March. Here a partial action took place, which ended in his defeat, and instant retreat to Seringapatam. That fortress was a few days afterwards regularly invested by the combined armies of the British and the Nizam. Tippoo now endeavoured to make peace; but as he was unwilling to accede to the terms proposed by General Harris, the siege continued. On the 4th of May, the fort was taken by assault. Tippoo was killed under a gateway, but by whom, or in what manner, is not known; no individual ever appeared to claim the honour of having slain him, nor was it ever discovered who had obtained possession of his valuable necklace of pearls. A great proportion of the garrison, which amounted to about 8000 men, was slain.

The talents of Tippoo were undoubtedly great; but he did not possess them in an equal degree with his father, and he was yet more ill-favoured with respect to prudence and knowledge of human nature. He succeeded best in attaching to him the lowest classes of the Mahomedans, and he possessed all the bigotry and zeal necessary for that purpose. None of his Mahomedan soldiers entered the British service, though many suffered extreme poverty, and they still revered his memory, regarding him as a martyr, who fell in the defence of their religion.

By the treaty with the Nizam, the fall of Seringapatam, and the death of Tippoo, the Mahomedan branch of the grand confederacy which the French had raised against the British in India, was completely destroyed.

As soon as Lord Wellesley learnt the fate of Tippoo, The Mysore sate divided, where he formed a plan for the partition of his country. This was carried into effect. The districts of Canara, including all the sea-coasts of Mysore, and the provinces immediately adjoining the possessions of the British on the coast of Malabar, and the Carnatic, were kept by the British; they also retained the forts and posts at the different passes into the Mysore, and the fortress and island of Seringapatam. The districts of Goorom, Condah, Gooty, and others contiguous to his dominions, were given to the Nizam. Lord Wellesley moreover resolved to cede some districts contiguous to the Poonah government, to the Paisiah, provided they would enter into a new treaty with him. Over what remain-
of the Mysore territories, Lord Wellesley placed the
descendant of the ancient Hindoo family of Mysore;
and, as he was an infant, a Brahmin of great ability and
reputation was appointed his minister. Two treaties
were formed with this prince. The first related to the
partition of the Mysore; the second to the relations
which were to subsist between the prince and the
British government. By this last treaty the British were
to maintain a military force for the defence of the
kingdom of Mysore against all external enemies; and
the Rajah agreed to pay an annual subsidy of seven lacks of
pagodas, for the support of this force. In case the Rajah
failed in executing his part of the treaty, or its
appearing probable that he might, the British govern-
ment were either to introduce such regulations in the
management of the revenues, or to assume such parts
of the country of Mysore, as appeared necessary to ren-
der the funds fixed for the maintenance of the troops
efficient and available. The Rajah also agreed to per-
mit the British to garrison with its own troops such
fortresses in Mysore, as it might think necessary to en-
able it to fulfil its engagements of defending that
kingdom.

On the 12th of October 1800, a new treaty was
formed between the Nizam and Lord Wellesley, by
which the former agreed, in consideration of a larger
British force being kept for his defence, to cede, in or-
der to secure the payment of this augmented force,
the British, in perpetuity, all the territories which he
had acquired by the treaty of Seringapatam in 1792,
and the treaty of Mysore in 1799; and the British
bound themselves to prevent any power from invading
the territories of the Nizam.

It has been stated, that the British government had
reserved a considerable portion of the territories which
they had conquered from Tippoo, to be given to the
Paishwah, on certain conditions; but he, having refused
to accede to the terms proposed, the reserved territory
was ceded between the British and the Nizam. Lord
Wellesley was still desirous of connecting the Paish-
wah more closely with the British; and a favour-
able opportunity to accomplish his wishes occurred in
the beginning of the year 1801. At this time a war
took place between Holkar and Scindiah, which oblig-
ed the latter to remove from Poonah, and consequently
weakened his influence with the Paishwah. The latter
seemed disposed to form an alliance with the British;
and indeed his territories were in such a weak and un-
settled state, that an alliance with them was highly de-
sirable. Hordes of banditti were daily pouring in from
Malwah and Hindostan, to contend at Poonah for the
sovereignty of the Mahratta empire. In 1802, the Paishwah,
der under these difficulties, united himself against Scindiah;
but his army sustained a signal defeat near
Poonah, on the 23rd of October. The Paishwah was
now more anxious than ever to place himself under the
protection of the British; accordingly, a definitive treaty
of alliance was concluded on the 31st of December,
at Bassein, where the Paishwah resided under the
protection of the British. By this treaty, the British
government bound itself to furnish to the Paishwah six
battalions of native infantry, with a suitable train of ar-
illery; and for the payment of this force, the Paishwah
agreed to cede territory to the amount of 26 lacks of rupees.
All his claims on Surat, and the English districts in Guzerat, were given up.

In order to support this treaty, which included the
restoration of the Paishwah to his throne at Poonah,
the army of Fort St. George, under the command of
General Stewart, advanced to the bank of the Toom-
budah, and General Wellesley was detached in front;
the latter advancing in cooperation with the subsidiary
force in the Deccan, commanded by Colonel Stevenson,
through the southern parts of the Paishwah's territor-
ies, reached Poonah on the 20th of April. The troops
of Holkar fled at his approach; and the Paishwah,
who had left Bassein, when he learnt that the British forces
were coming to his aid, entered Poonah, and was re-
seated on his Musnad, on the 13th of May. This meas-
ure was effected without any opposition: and all the
principal Mahratta chieftains, who are the more im-
mediate feudatories of the Paishwah, joined their troops
to those of General Wellesley, and advanced with him
to Poonah, where they paid their obeisance to the
Paishwah.

As Holkar had fled on the advance of General Wel-
lesley, it was hoped that the Paishwah would be allowed
to sit quietly on his Musnad. These hopes, however,
were soon disappointed; for Scindiah, after remon-
strating against the advance of the British troops to
Poonah, and finding his remonstrances disregarded,
Marched towards the frontiers of the Nizam. Lord Wel-
lesley at first endeavoured to negotiate with Scindiah,
but not succeeding, he vested the officers in command
of the armies in Hindostan and the Deccan, with the
fattest civil, military, and political powers. General
Wellesley was authorized to negotiate treaties with
Scindiah, Holkar, or the Rajah of Berar; and Lord
Lake, who was at the head of the Hindostan army, was
directed, in the first place, to reduce the formidable and
independent French authority which had been estab-
lished there; and then to occupy the whole country,
forming the Doob, between the Jumna and the
Ganges, to the mountains of Cumaoun, and also to take
possession of Delhi, Agra, and a chain of posts on the
right banks of the Jumna, from the mountains of Cu-
maoun, to the province of Bundelcund.

The first operation of the war was the reduction of
the fortress of Ahmednagar, on the 8th of August, by
General Wellesley; this success was followed up, both
by him and by Lord Lake, by the most splendid
and decisive victories, especially those of Assaye and
Arghaum by the former, and those of Delhi and Laswarse by the latter. The battle of Assaye was
fought near that town, which is situated in the
province of Berar, on the 23rd of September. Gen-
eral Wellesley's army consisted of 4500 men, of which
number 2500 were Europeans; the armies of Scindiah
and the Rajah of Naggooor amounted to 30,000 men.
The battle was obstinate, but at length the allied
troops gave way and fled in great confusion: 1200
of them were killed on the field; 98 pieces of can-
non, seven standards, their camp equipage, a large
quantity of ammunition, &c. were taken. General
Wellesley immediately followed up his success; and on
the 28th of November was fought the battle of Ar-
ghaum, equally splendid and decisive in its results with
the battle of Assaye. These defeats led both Scindiah
and the Rajah to solicit peace; and the latter, imme-
diately after his principal fortress, Gavleghur, was
reduced, made peace with General Wellesley. In the
agree he was compelled to submit to very unfavourable
terms: the province of Cuttack, and that part of the
province of Berar to the west of the Wurdah, which
belonged to him, were ceded to the British; he also
promised not to permit, for the future, any person be-
ong to a European or American state, at war with
Britain, to be in his service.

Scindiah thus beaten and deserted by his ally, sued
for peace, which was granted him in December 1803.
He gave up to the British all his territories in Hindostan, which lay to the southward of those possessed by the Rajahs of Jypore, Joudpour, and the Rani of Gohud; he also ceded the lands to the south of Adjuttee, and the fort and territory of Barooch; and he resigned all claims which he had on the British and their allies.

During this war, Holkar had remained quiet and inactive, though he had engaged to assist the allies against the British. As Lord Wellesley was informed of this circumstance, he deemed it indispensably necessary to obtain from this chief an early and satisfactory explanation of his views and plans. This, however, Holkar at first evaded, and afterwards made such proposals for a treaty with the British, as Lord Wellesley could not accept. These proposals being rejected, Holkar openly prepared for hostilities: he endeavoured to persuade Scindiah to assist him in an attack on the British territories; and at the same time invaded and plundered the country of the Rajah of Jypore. Lord Lake immediately advanced against him, but he retreated from the position which he occupied. The war with Holkar was distinguished by the suddenness and rapidity of the movements by which he for a long time contrived to elude the attacks of the British, though his territories were invaded by them in every direction; and by the reverses which attended the British army. Two corps under the command of Colonel Monson, and Colonel Murray, had been sent against the capital of Holkar's dominions: the latter arrived at it, and succeeded in reducing it; but the former having been led astray by his guides, was attacked by Holkar with such a decided superiority of force, that he was compelled to retreat towards Agra: at first the retreat was conducted with a good deal of order; but afterwards, in consequence of several conflicts in which the British suffered severely, and the loss of most of their artillery, ammunition, &c. they retreated in the utmost confusion. As the country was nearly impassable from the rains, Colonel Monson did not reach Agra till after the space of seven weeks; and then only a very few of his troops entered it, the rest having been either killed by the enemy, or having perished through fatigue.

Holkar hitherto had eluded all attempts of General Lake to bring him to battle; but at length, having encamped his army under the walls of Deog, in the province of Agra, with several ranges of batteries before them, to the depth of two miles, he resolved to wait the attack of the British. The attack was made with complete success. Holkar's regular infantry and artillery were nearly all destroyed; and after a short but vigorous siege, the town surrendered to the British.

In order that he might have time to collect his scattered troops, Holkar persuaded the Rajah of Bhurpopoor to embrace his cause. As the reduction of this fortress was deemed an object of great importance, General Lake sat down before it; but the defence made by the garrison proved most obstinate. They repulsed with great slaughter the assaults of the besiegers; so that in the course of the siege the loss of the British exceeded that which they had sustained in any three of the greatest battles they had fought in India. At last the Rajah sued for peace, which was granted him on condition that he paid to the British 20 lacks of rupees, five immediately, and the remainder by instalments.

Notwithstanding the defeats which Holkar had sustained, and the desertion of nearly all his allies, he still persevered in the war; but he conducted it more like the chief of a band of marauders, than the general of an army. In his last campaign, he entered the British territories to the westward of Delhi. Lord Lake immediately marched after him, but on the approach of the British he fled; and his flight was uninterrupted and most rapid, till he reached the banks of the Beyah, in the Punjab, when, being reduced to the utmost distress, he solicited peace from Lord Lake. The treaty was ratified on the 8th of January 1806, by which he gave up all claims on Koonaah and Bundelcund, and the districts north of the Chumbul; the latter, however, were afterwards given back to him.

Before Holkar was finally overcome, Lord Wellesley had left India. We have briefly related the military transactions which took place during his government; but it will be also proper to advert to those changes in the British possessions in India, which he effected without the aid of war.

In November 1801, all the frontier provinces of Oude were ceded to the Company. The reason assigned for this cession was, that the British possessions might become a barrier between the dominions of the vizier of Oude and any foreign enemy. On the 25th of July 1801, the civil and military government of the Carnatic was given up to the British, on condition that they should pay the debts of the Nabob, and allow him an annual sum, equal to one fifth of the revenues of the Carnatic.

At the period of Lord Wellesley's departure for England, the allies of the British were more secure, and their enemies less numerous and formidable than they had ever been before. Of the former, the Souabhadr of the Decan was the most important; and he had been placed in a situation of security, by the reduction of the Mahratta chiefs, and by maintaining within his territories a subsidiary European force. The sovereign of Mysore was now friendly to the British, instead of being one of their most inveterate enemies. The two Presidencies of Madras and Bengal were connected by the conquest of Cuttack; and this conquest, together with the territories which the British now possessed in Guzerat, Malabar, and Canara, rendered them the masters of nearly all the sea coast from the mouths of the Ganges to those of the Indus.

In Hindostan proper, the influence of the French was completely destroyed; the incursions of the Mahrattas into it had been effectually checked, and were not likely to be soon renewed; as by the territories ceded to the British in the Doob, and on the right banks of the Jumnah, as well as by the protection which the British gave to those small states which stretch from the mountains of Cumaon to Bundelcund, the British provinces were defended from the encroachments of the Mahratta chiefs.

On the 31st of December 1805, during the administration of Sir George Barlow, a new treaty was concluded with Scindiah, by which that chief gave up all claims on the countries of Boondee, Surreedee, Dhoopoor, Barree, and Rajah Keriah.

During the administration of Lord Minto, the only events of importance which occurred in India, were the reduction of Java, for an account of which see Java; the renewing of the British protection to the Seik chiefs on the north-west of the Jumnah, and the south of the Sutlej, thus strengthening and extending the frontier of the British territories in Hindostan; and the protection afforded to the Rajah of Berar from the attacks of Meer Khan, a chieflain of Malwa, and a noted pirate, or freebooter.

Lord Minto was succeeded in the government of In-
PART III. STATISTICS.

CHAP. I. Extent—Boundaries—Divisions.—Progressive Geography.

We have already mentioned the grand divisions of Hindostan, into North Hindostan; Hindostan Proper; the Decan; and the South of India; and the boundaries of the whole, as well as of each division. We have also mentioned, that this article will be confined to Hindostan proper, the Decan, and the south of India; referring the reader, for information respecting Northern Hindostan, to the articles Cashmere, Nepaul, Bootan, Tibet, &c.

Taking Hindostan in the largest acceptance of the term, its area comprehends about one million geographical square miles, or an extent equal to the whole of Europe, with the exception of Denmark, Norway, Lapland, Sweden, Russia, and Poland. Hindostan proper is equal in size to France, Italy, Germany, Bohemia, Hungary, Switzerland, and the Netherlands; and the Decan, and the south of India, are about equal to the British islands, Spain, and Turkey in Europe.

Hindostan Proper contains eleven provinces. 1st, Lahore. The boundary of this province on the west is the Indus, by which it is separated from Afghanistan; on the east the river Sutlej, a subsidiary stream of the Indus, divides it from Northern Hindostan; on the north it is bounded principally by Cashmere; and on the south by the provinces of Multan, Delhi, and Ajmeer. Its length is about 320, and its breadth about 30 miles. From the 32° to the 34° of north latitude it is mountainous; from the 32° to the 30°, its southern limit, it is flat, constituting what is called the Punjab, a natural division of Hindostan proper, which we shall afterwards notice. The greatest part of Lahore belongs to the Seiks. The city of Lahore is the capital of the province; but Amretair is the capital of the Seik nation. 2. Multan, which lies between the 28° and 31° of north latitude, is bounded by both Hindostan and Afghanistan on the north; by Ajmeer and Sind on the south; by Belochistan on the west; and by Lahore and Ajmeer on the east. Its extent is not accurately ascertained. It is possessed by several petty princes, of whom the nabob of Multan is one of the principal; but they are continually exposed to the incursions of the Afghans, Seiks, &c. and are also almost always fighting with one another. Multan is the capital of this province. Sind is generally regarded as part of the province of Multan, though it ought with more propriety to be regarded and described as a separate province. Sind lies on both sides of the Indus. The eastern division, the only one which we are called upon to notice in this article, is bounded by Multan and Afghanistan on the north; Cutch and the sea to the south; Cutch, the Sandy Desert, and Ajmeer, on the east; and the Indus on the west. The whole of Sind is governed by a prince of the Talpoony family; but one of his brothers, though nominally dependent upon him, exercises all the powers of sovereignty over the districts on the eastern banks of the Indus. 3. Guzerat. Guzerat is bounded on the south chiefly by the sea, and in a small part by the Decan; on the north by Ajmeer; on the east by the Gulf of Cambay, and the provinces of Malwah and Khandesh; and on the west by the Gulf of Cutch, the province of Cutch, and the Sandy Desert. It lies between the 21° and 24° of north latitude. Its length from north to south is about 320 miles; its
breadth varies very much, but on an average it may be 180 miles. Those parts of this province which are the best cultivated, are in the possession of the British, the Paishwah and the Guizowar. The territories of the first stretch along both sides of the Gulf of Cambay, and comprise the cities of Surat, Baroa, Cambay, and Gos. The sea coast from this gulf to the mouth of the Indus, is governed by a number of petty princes. The principal fertile tract in Guizowar, retained by the British, are Ahmedabad, which belongs to the Paishwah, and Champzeer, which belongs to a Mahatta chief called the Guizowar, whose dominions lie in this part of the province. Cutch may be considered in connection with Guizowar, which lies to the east of it. On the west it is bounded by Tatta, a district of Sind; on the south by the Gulf of Cutch; and on the north by the Sandy Desert and Sind. Its length is supposed to be about 110 miles, and its average breadth about 70. It is entirely possessed by a number of tribes, who live by plunder and piracy.

Agra.

Agra, situated between the 28th and 31st degrees of latitude, is bounded on the north by Lahore, and some districts in northern Hindustan Proper; on the south by Agra and Ajmere; on the west by Ajmere and Lahore; and on the east by Oude, and the hills which divide it from northern Hindustan. Its length is about 240 miles, and average breadth about 180. The city of Delhi, with a tract of country round it, the whole of the province to the east of the Jumna and the north-eastern division of it, belong to the British. The southern districts belong to various rajahs, all of whom are allies of the British. The Sikhs principally occupy the tract to the north-west of the Jumna, and south of the Sutlej. The principal towns are Delhi, Sawal, Hisar, Sarahanpoor, &c. 6 Agra, between the 28th and 31st degrees of latitude, is bounded on the north by Delhi; on the south by Malwa; on the east by Ajmeer; and on the east by Oude and Allahabad. Its length is 150 miles, and its average breadth 180. Several rajahs, who are allies of the British, possess the north-western and western districts. The city of Agra, a small district round it, and the country to the east of the Jumna, belong to the British; the rest of the province, with a trading exception, is possessed by the Maratta. The principal town besides Agra, are, Bharipur, Dung, two strong fortresses; Canee, Kalpy, and Narwar. 7 Malwa, between the 22nd and 24th degrees of latitude, is bounded on the north by Ajmeer and Agra; on the north by Khandeech and Harer; on the east by Allahabad; and on the west by Ajmeer and Guizowar. Its average breadth is about 150 miles, and length 250 miles. It is occupied almost entirely by Scindiah and his tributary chieftains. Allahabad also possesses a small portion of this province. The principal towns are, Indere, Munde, Bospal &c. 8. Allahabad, between the 24th and 26th degrees of latitude, is bounded on the west by Malwa and Agra; on the east by Bahar and Gundwana; on the north by Oude and Agra; and on the south by Gundwana. Its length is about 270 miles, and its breadth averages about 120. Nearly the whole of this province belongs either to the British, or to their ally the nabob of Oude. The principal towns are, Allahabad, Benares, Callinger, Chunnar, &c. 9. Oude, between the 26th and 28th degrees of latitude, is separated, on the north, by a range of hills from Nepaul; on the south it is bounded by the Ganges, into two portions, nearly equal; one of them stretches 70 miles from that river to the Ganges, breadth 100 miles. The whole of this province is either possessed in full sovereignty by the British, or, though still held nominally by the Nabob, entirely under their protection and control. The principal towns are, Lucknow, the capital and residence of the Nabob, Fyzabad, the former capital, Oude, Goorapoor, &c. Bh. Oude, between the 26th and 27th degrees of latitude, is divided, on the north, from Nepaul by a range of high hills; on the south is bounded by Gundwana; on the east by Bengal; and on the west by Allahabad, Oude, and Gundwana. It is 250 miles long, and 200 broad. According to Mr J. Grant, in his Supplement to the Historical and Comparative Analysis of the Finances of Bengal, &c. published in the Appendix to the Fifth Report from the Select Committee of the House of Commons, there are in this province 26,000,000 square British miles of plain arable land, out of 51,973 the total superficial contents. This plain country is naturally divided by the Ganges, into two portions, nearly equal; one of them stretches 70 miles from that river to the forests of Nepaul and Murung, at the foot of the Tibetan mountains; the other division stretches from the Ganges southward, to the hills which lie between the lower plains and the Himalaunts, or country above the Ghauts. To the south of these two divisions of Bhahar, there is a district, almost entirely covered with detached and straggling hills, the area of which comprises 5000 square miles; and, still further to the south, there is a hillyland district, which, since the age of Tolemy, has been divided into three belders, or cantons. The British possess the eight districts into which the plain country, north and south of the Ganges, is divided; as well as the greatest part of the hillyland districts. The principal towns are Patna, Mongur, Buxar, &c. 11. Bengal, between the 21st and 27th degrees of latitude, is bounded on the north by Nepaul and Bostan; on the south by the bay of Bengal; on the east by Assam and Ava; and on the west by Bucker Mahanpoor, a district formerly belonging to the province of Orissa, is now deemed part of Bengal; and, if this be included the length of Bengal will be 250 miles, and its average breadth 200. The whole of this province belongs to the British. The principal places in it are Calcutta, Dacca, Moorshehabad, Haoghly, Cominabur, Munda, &c. 2. The Decan. 1. Aurungabad, between the 18th and 21st degrees of latitude, is bounded on the east by the sea; on the east by Berar and Hyderbad; on the north by Berar, Khandeech, and Guizowar; and on the south by Bijapoor and Bedar. Its length is about 500 miles, and its average breadth 160 Bombay and Salsette belong to the British. Of the mainland, the Paishwah and his feudatories possess nearly three fourths; and the other fourth belongs to the Nizam. The principal towns are Aurungabad, Ahmednagar, Bascoio, Dumman, and Dawletsabad. 2. Khandeech, between the 21st and 27th degrees of latitude, is bounded on the north by Malwa; and on the south by Aurungabad and Berar; on the east by Berar; and on the west by Guizowar. Its length is about 200 miles, and its ave-
The principal towns are Boorhanpoor, Hinda, and Asser. It is full of strong fortresses. 3. Beder, between the 16th and 18th degrees of latitude, is bounded on the north by Berar; on the south by Hyderabad and Berar; on the west by Bejapoar; and on the east by Hyderabad. Its length is 140, and its breadth averages 65 miles. It is wholly possessed by the Nizam. Its principal town is Ahmednabad, built near the ruins of the ancient city of Beder. 4. Hyderabad, between the 16th and 18th degrees of latitude, is bounded on the south by These, on the north by the Godavery; on the west by Bejapoar and Aurungabad; and on the east by Gundwana. Its length is 180, and its average breadth 150 miles. It belongs entirely to the Nizam.

The principal towns are Hyderabad, the capital of the Nizam's territories, Golconda, Warangol, &c. 5. Nandere. This small province, lying in about the 19th degree of latitude, is bounded on the north by Berar; on the south by Hyderabad and Berar; on the west by Aurungabad; and on the east by Gundwana. It belongs entirely to the Nizam. The principal towns are Nandere, Candhar, Balanad, &c. 6. The Northern Circars, a narrow slip of maritime country, extending from the 15th to the 20th degree of latitude, is bounded on the east by the sea; it is divided from Hyderabad on the west, by a ridge of small detached hills; from Berar, on the north, by another ridge of a much greater height, and nearly impassable; and from Orissa on the north-east by the same hills, and the Chilka lake; the river Gundezama divides it, on the south, from the Carnatic Payenghaut. The length of this province is about 470 miles, and its breadth varies from 50 to 70 miles. In the year 1765, four of the circars were ceded to the British; and in 1788, the remaining circar came into their possession.

The principal towns are Banjam, Visagapatam, Masulipatam, and Guntour. 7. Berar, between the 19th and 22d degree of latitude, is bounded on the south by Nandere, which is frequently included in it; on the north by Khandeish and Allahabad; on the east by Gundwana; and on the west by Khandeish and Aurungabad. If Nandere be considered as part of it, its length will be 230 miles: its average breadth is 120. Three fourths of it belong to the Nizam, and the remainder to the Maharrats. The principal towns are Elichpooor, Gavelghur, Poonar, &c. 8. Gundwana, lying between the 19th and 25th degrees of latitude, is bounded on the north by Allahabad and Bahr; on the south by Orissa and the Godavery; on the east by Orissa, Bengal, and Bahr; and the west by Malwa, Berar, and Allahabad. It is 400 miles long, and 250 miles in average breadth. The fertile districts of this province are held by the Nangpoor Maharrats; the mountainous and barren parts are still in the possession of the native inhabitants, called Goards. The principal towns are Nangpoor, Gurrah, &c. 9. Orissa, lying between the 16th and 23rd degrees of latitude, is bounded on the north by Bengal and Bahr; on the south by the Godavery and the Circars; on the east by the bay of Bengal; and on the west by Gundwana. Its length is about 530 miles, its average breadth not exceeding 90 miles. Three-fourths of Orissa belong to the British; the rest is possessed by several native chiefs, over whom the Nangpoor Maharrats claim the sovereignty. 10. The greatest part of the province of Bejapoar lies to the north of the Krishniah, and consequently may justly be considered as a province of the Decan. It stretches from the 15th to the 19th degree of latitude. It is bounded on the south by the Toombuddra, a branch of the Krishniah, and North Canara; on the north by Aurungabad; on the east by Aurungabad and Beder; and on the west by the sea. Its length is about 350 miles, and its average breadth 200. Four-fifths of this province belong to the Poonah Maharrats; and of this part the Paishwah possesses in full sovereignty little more than the maritime district of Concan. The Nizam possesses the remaining fifth. The principal towns are, Poonah, Bejapoar, Darwar, Mirjee, &c. 11. The South or India,—Bejapoar, a small part of Provinces which lies in the great division of India, has been al-
labar is a particular part of the coast of Malabar to which this name is appropriated. It is situated between the 10th and 13th degrees of latitude. On the north it is bounded by the province of Canara; on the south by Cochin; on the east by the Ghauts; and on the west by the sea. Its length is about 135 miles, and its average breadth about 35. The whole of the province belongs to the British. The principal towns are Calicut, Vembanad, and Panany. 6. Baramahal, situated between the 12th and 14th degrees of latitude, and bounded on the west by the Ghauts, and on the east by the sea, belongs entirely to the British. 7. Coimbetoor is bounded on the north by the Mysore; on the south by Dimilgul; on the east by Salem and Kistnagerry; and on the west by the province of Malabar. It lies entirely above the Ghauts. It belongs entirely to the British. The principal town is Coimbetoor. 8. Dindigul lies between the 10th and 11th degrees of latitude; and is bounded on the north by Coimbetoor and Kivnagerry; on the south by Travancore and Madura; on the east by the southern Carnatic and Madura; and on the west by Travancore, Cochin, and Malabar. It belongs entirely to the British. The principal towns are, Dindigul, Balmy, and Palapetty. 9. Cochin is a very small province, bounded on the north by Malabar; on the south by Travancore; on the east by Dimilgul; and on the west by the sea. The Rajah of Cochin is tributary to the British. The principal town is Cochin. 10. Travancore is bounded on the south and the west by the sea; on the north by Cochin; and on the east by the Tinnevelly district of the southern Carnatic. It lies between the 8th and 10th degrees of latitude. Its length is about 140 miles, and its breadth about 40. The Rajah of Travancore is subject to the British. The principal towns are Anjenjo, Coitan, and Travancore.

Such are the geographical divisions of Hindostan. There are, however, natural and political divisions, which it will be proper to notice.

Of the natural divisions, the Punjab is one of the most celebrated in history, as well as one of the most striking in its character. The Punjab is sometimes considered as consisting only of the flat portion of the province of Lahore; but, in its proper and most extensive meaning, it comprehends all that tract of country to the west of the Himalaya Mountains, through which the principal tributary streams of the Indus run. Its south-eastern boundary is formed by the Satlaje; and, from this river to Attak on the Indus, its breadth is computed to be 235 geographical miles. Its length from north to south has not been ascertained. The Doab is another natural division of the country, which frequently occurs in the history of Hindostan. The term Doab properly means any tract of country included between two rivers; of course there are many Doasas in Hindostan; but the term is emphatically applied to the country between the Jumna and the Ganges, or, in its strictest sense, to the southern portion of that territory, for the most part comprehended in the province of Agra. The Delta of the Ganges and the Indus are also natural divisions of Hindostan. The former commences about 260 miles from the sea. The lower part of it is called the Sunderbunds, and extends along the bay of Bengal about 180 miles. The Sunderbunds are almost entirely formed of woods, interspersed with creeks, and numberless islands, and salt marshes. This tract is in extent equal to the principality of Wales. The Delta of the Indus is about 150 miles in length along the sea-coast, and about 115 from the point of separation of the superior branches of the river to its most prominent mouth. The lower part of the Delta of the Indus resembles the lower part of the Delta of the Ganges, in being intersected with rivers and lakes; but there are no trees on it, the greatest part being sandy, or covered with swamps and stagnant lakes. The last natural division of the country which we shall mention, is the Table land in Central and Table land. Southern Hindostan. This is supported by the eastern and western Ghauts. It stretches not only through the Mahratta territories, but also through the peninsula to the southern extremity of Mysore. Properly speaking, however, it is not table land, as the surface is considerably varied, being broken into hill and dale.

In the geographical description which has been given of the different provinces of Hindostan, mention has been made of the powers by whom they were possessed. It will be proper, however, to bring into one view the political divisions of the country, by exhibiting a connected account of the possessions held by the British; the princes tributary to the British; the independent princes; and the petty chiefs.

The British possessions are divided into three presidencies, Bengal, Bombay, and Madras. Bengal is the supreme presidency, and in it are comprised the whole provinces of Bengal and Barah; three-fourths of the adjoining province of Orissa; the districts of Benares, Allahabad, and Barenpur in the province of Allahabad; a small part of Barar; and a great portion of the territories of the Nabob of Oude, ceded by the treaties of November 1801; the eastern and north-eastern districts of Delhi, and that part of Agra which lies to the east of the Jumna, are also under the Bengal presidency. The Bombay presidency extends its influence over the whole western coast of India; but the possessions under its absolute and immediate jurisdiction are of trifling extent, compared with those subject to the presidencies of Bengal and Madras. They consist of the districts of Surat, Barosch, Cambay, Goswaraeh, and in general the tract which lies along both sides of the Gulph of Cambay, comprehending the most fertile and populous part of the province of Guzerat. Under the presidency of Madras, the whole of India south of the Krishnna, and the northern Circars in the Decan, are placed. The Rajahs of Mysore, Travancore, and Cochin, indeed collect the revenues, and direct the internal policy of their respective states; but they are, in fact, vassals of the British in every thing relating to external politics. In the northern Circars, there are five districts; in the Carnatic, six. Part of Mysore and the southern Carnatic form one district. Tinnevelly, in the southern Carnatic, constitutes another district; and, in the rest of the Mysore, there are eight districts: in all, 21 districts under the Madras presidency.

The Nizam possesses the centre of the Decan, his dominions comprising the greater part of Berar, the whole of the province of Hyderabad, Nandore, and Bedar, and part of Aurungabada and Bijapur. His territories are divided from those of the British by the Krishnna and Toombulba; and from those of the Nagpores Rajah by the Wurdeh. Their length is about 460 miles, and their average breadth 260. The Nizam is one of the principal of the British allies.

By the treaty of the 31st of December 1802, between the Paishwah and the British government, the federal power of the Mahrattas was annihilated, and the independent state of the Paishwah, the Rajah of Nagpore,
Seindiah, Holkar, and the Guicowar, were established and recognised. The territories of the Paishawah are by no means extensive; they lie in Guzerat, where they are much intermixed with those of the British; above the Ghaus, to the north and west of Poonah; and in the provinces of Bejapoor, Aurospabad, and Allahabad. Poonah is his capital; he is still the nominal head of the Maharratas. The Mahratta chieflain, known by the family name of the Guicowar, possesses the northern districts of Guzerat; his capital is Brodah; he is also an ally of the British. The Nabob of Oude is completely dependent upon the British; a great part of his dominions having been ceded by him to them, and they also having the right of interfering at pleasure in the administration of his remaining provinces. The districts of Lucknow and Oude still belong to the Nabob; the city of Lucknow is his capital and residence. The Mysore Rajah's dominions are divided into three great districts, one of which alone contains a greater extent of territory than was originally subject to his family. The Rajahs of Cochin and Travancore, who are also tributaries to the British, possess the territories already described under the geographical divisions of Cochin and Travancore.

Seindiah. Seindiah is one of the most powerful independent princes of Hindostan; the greater part of the province of Malwah belongs to him: Osajain is the capital of his dominions. The Rajah of Nagpoor, the chief of the Benares Mahrattas, possesses the greater part of the ancient Hindoo province of Bundwan; his territories bordering on Bengal, the Northern Circars, and the Nizam possessions in the Deccan. Over this extensive tract of country he has a nominal territory; but his actual power does not reach much beyond the vicinity of his capital, Nagpoor.

Rajah of Nagpoor. The Seiks inhabit and possess the territory that extends from 28° 40', to 32° 20' North Lat. comprehending the whole of the Punjab, a part of Multan, and those districts of the province of Delhi which lie between the rivers Jumna and the Sutlej. Their dominions are bounded on the north by Caubul; on the east by the territories of some petty Rajahs in the mountains parts of Lahore; on the south by the British provinces, and on the west by Caubul. The Seiks between the Jumna and the Sutlej are called Malawah Singhss; those bordering on the Indies, Sind Singhss; and those residing in the province of Multan, Nakai Singhss. The province of Sind is almost entirely possessed by five Ameers, or noblemen of the Talpooy family; that part of the province which is, properly speaking, in Hindostan, is governed by Meer Sohrab, and his brother Meer Thora; the districts subject to the authority of the former are situated on the north-east quarter of Sind; those belonging to the latter lie more to the south, on the eastern banks of the Indus; these brothers, however, are subject to the authority of another Meer, who has the title of hakim, or ruler of Sind, and is regarded as the head of the government. The dominions of the Rajahpoot princes are situated on the north-west side of Hindostan, and principally in the central division of the province of Ajmeer. The eastern quarter of this division is subject to the Rajah of Jegenaor; the south eastern to the Rajahs of Kolah, Boonde, and other chiefs tributary to the Mahrattas; the western parts to the Rajah of Joodpoor, and the south western to the Rana of Odypeer.

The following Table, given by Mr Hamilton, exhibits, at one view, the extent of territory possessed by the different modern rulers of Hindostan; it will be ob-

| Total of Hindostan | 1,029,000 |

The first notice of India by the ancient authors is given by Herodotus: Prior to the invasion of that country by Darius Hystaspes, the Persian monarch sent Scylax of Caryanda to trace the course of the Indus, and ascertain the place where it discharged itself into the sea. From his account, Herodotus was supplied with his knowledge of India, but it evidently does not extend beyond the sandy tract which lies east of the Indus and south of the Punjab. The conquests of Alexander supply us with the next step in the progressive geography of this country: he is generally supposed to have crossed the Indus at Attock; but Major Wilford is of opinion that he crossed at the ferry of Torbeilam, a few miles to the south of Attock; from the east side of the Indus, he advanced to the Acesines or Chunaub, which he crossed, and also the Hydrosales or Rauy. After this he deviated from the direct road leading to the Ganges, and advanced in a south-westerly route to Sangala; from this place he turned again to the east, and reached the Hyphasis Beyah. This was the limit of his march; and consequently the information which Arrian and other historians afford respecting India, derived from his victories, does not extend beyond this tract of country; that is about 200 miles across the Punjab, or the modern province of Lahore, and the countries which, on his return, Alexander traversed from Multan to the sea. Our first knowledge of the Ganges is derived from Megasthenes, who was sent ambassador by Seleucus to Chandragupta or Sandracottus, king of the Frasi: the
capital of this kingdom was Palebrotha, generally supposed to be Patna, on the south side of the Ganges, in latitude 25° 57', and longitude 83° 15'. In this city Megasthenes resided three years, and as he kept a journal of what he saw and heard regarding India during his residence, it may be supposed that his information added very much to the knowledge which the ancients possessed of India. Diodorus Siculus, Arrian, &c. Strabo, Arrian, and Pliny seem to have derived all the accounts which they gave of India from Megasthenes. All these authors lay down the proportional dimensions of this country with tolerably accuracy. According to Diodorus, the breadth is seven-eighths of the length. Arrian's geography of India is principally confined to the northern parts, which had been visited by Alexander and Megasthenes: he gives a tolerably accurate account of most of the rivers which flow into the Indus and Ganges; and the extent of India, which he derived from Megasthenes, is as near the truth, according to Mr Rennel, as that which we assigned it 60 years ago. Pliny was evidently acquainted with the form of the Peninsula, from the measures which he gives along the coasts between the mouths of the Ganges and the Indus. One of the most important ancient records of this country, is to be found in the map and description of Ptolemy. In some respects this author is very minute and accurate; but in other respects he is most grossly erroneous: though he lived 60 years after Pliny, he describes the peninsula of India as stretching from the gulf of Cambay from east to west, instead of extending from north to south. This is the more extraordinary, not only because he had access to the comparatively accurate information respecting India, recorded by Strabo, Diodorus Siculus, and Pliny, but because he himself traces, with great minuteness, the sea coast, specifies the most remarkable places on it, and assigns the latitude and longitude of each from Cape Comorin to the mouth of the Ganges. Hence it would appear, that his general account of the form of India was expressly contradicted by his detailed description of the country. To Ptolemy also we are indebted for the enumeration and relative position of the different mouths of the Ganges; and for a curious delineation of various roads used by the traders to China, across the north of Hindostan. The geography of this part of Hindostan is also greatly illustrated by the description given by Pliny, Dio Cassius, Plieregetes, Ptolemy, and the Peutingers tables of the Persian royal or Nyssan road. This was made with great care, and at the end of every Indian itinerary measure a small column was erected. The first part of it corresponds with the route pursued by Alexander from the Indus to the Hyphasis; the remainder led to Palebrotha: its whole length was nearly 1500 miles. This road has been illustrated with considerable learning, but not always with the soundest judgment, by Major Wilford.

After the age of Ptolemy, we derive no additional or more accurate information regarding India, till the 6th century after Christ. At this period Cosmas, an Egyptian merchant, made some voyages to India. From his work, it appears that he was well acquainted with the west coast of the Peninsula, which he particularly mentions as celebrated for its trade in pepper. After this time, till the discovery of the Cape of Good Hope, the geography of India is almost entirely illustrated by the Arabian writers, particularly by two Mahomedan travellers in the 9th century, whose travels have been published by Iremadot; by Massoudi, and by another Arabian author, who wrote about the middle of the 14th century. The Mahomedan travellers mention a great empire on the Malabar coast: their relation in this and other respects is confirmed by Massoudi, who published his account of India in the 10th century. This last author describes India as divided into four kingdoms; the first comprised the provinces on the Indus and its tributaries: the second was the capital. The second kingdom seems to have lain on the banks of the Ganges; of this, Kanoge was the capital. This kingdom and its capital are much celebrated in the most remote times of ancient Hindoo history. The third kingdom was Cashmire; the fourth was Guzerat. From this description, it is evident that the information respecting India possessed by Massoudi, and probably by his countrymen in general, was confined to Hindostan proper. The Arabian author who wrote about the middle of the 14th century, divides into the northern part, comprehending all the provinces on the Indus; the middle, which stretched across from Guzerat to the Ganges; and the southern, which he calls Comar, probably from Cape Comorin. About the middle of the 13th century, Marco Polo visited different parts of Hindostan: he is the first author who mentions Bengal and Surat by their present names, as rich and powerful kingdoms.

The next illustration of the geography of Hindostan is derived from the Ayin Aabearee, a work which we have already mentioned under the reign of the Emperor AÆbus. This sovereign divided Hindostan Proper into eleven soubars or provinces, which were again divided into circars, and these subdivided into parjwals. Cabul, and the countries west of the Indus, constituted a 12th soubar; and the conquests in the Decan afterwards were divided into three more. The details given in the Ayin Aabearee, of the extent, boundaries, divisions, productions, military force, &c. of these provinces, is surprisingly minute, and apparently the result of much attentive and laborious investigation and inquiries. But our object is only to notice such provinces as have a different extent assigned to them in the Ayin Aabearee from what is assigned to them at present, in order that we may thus illustrate the progressive geography of Hindostan. In the reign of Aebbar, Multan was one of the largest provinces of the empire, extending to the frontiers of Persia, and also comprehending several of the Doobs now belonging to the province of Lahore. The province of Ajmeer at present extends rather more to the south than it did in the reign of Aebbar, when this part of it was probably possessed by independent Rajpoot princes. In the soubar of Bengal are included Orissa and Cuttack, with the country to the south-east as far as Chittagong. Malwah, instead of being bounded on the south by Khandeish and Berar, extended beyond the Nerbuddah, while on the south-west and south it touched on Baglana, and on Berar on the east. The very ancient limits of Guzerat included the greater part of Khandeish and Malwah; and in the reign of Aebbar, it extended southward to Damaun, where it touched on Aurungabad. The present province of Nandere was comprehended in that of Berar, while the western parts of the latter do not seem to have been conquered by Aebbar. The province of Khandeish differed in its dimensions and boundaries only very little from what it is at present, then having Aurungabad on the west, instead of Guzerat, which now bounds it on that quarter. The province of Aurungabad, which in the time of Aebbar was known by the name of Ahmedagur, having been partially conquered by that monarch, its boun-
daries were constantly fluctuating; nor were they permanently fixed, till the capital having been taken in 1634, the whole of the province was annexed to the Mogul empire.

Notwithstanding the conquests and settlements of the Portuguese in India, yet as they were almost entirely confined to the sea coast, they did not much increase the geographical knowledge possessed by Europeans respecting this country. Indeed, till the conquests of the English, during the middle and latter end of the 18th century, little was accurately known respecting the interior of Hindostan. In 1788, Major Rennell published the first edition of his Memoir of a Map of Hindostan; in this work, with wonderful research and information, though not always with the most perspicuous or satisfactory arrangement, he has thrown great light on the geography of this country; and except with regard to those districts which at that time had been little, if at all explored by the English, he left scarcely any point uninvestigated. In the subsequent editions of his Memoir, as well as in the Oriental Repository of Dalrymple, the Asiatic Researches, the valuable Travels of Dr Francis Buchanan, and other authors, the geography of Hindostan has received such ample and minute investigation, as to leave very few parts of that extensive country unexamined.

CHAP. II.

Face of the Country.—Mountains.—Plains.—Deserts.—Rivers.—Lakes.—Canals.—Sea Coast.

The general description of the face of the country may be given in a few words. In Hindostan Proper, it is for the most part champagne, with occasional hills of no great elevation. In the Dekan and the south of India, it is flat near the sea coast on both sides, and mountainous in the interior. But it may be satisfactory to give a more regular and minute description of the face of the country. If we enter Hindostan at the north-west corner into Lahore, the face of the country is hilly, till we reach the southern extremity of this province, where the Punjab commences; passing thence to Multan, we again meet with hills in its northern extremity. The face of the country in Ajmeer is nearly the same, but when we pass to the south west into Guzerat, the surface is very flat; on the contrary, if we pass into the south or south-east, into Malwah, we enter a very elevated region, one of the most elevated, indeed, in Hindostan, as the rivers flow from it in every direction. If from the province of Lahore we change our route, and enter Delhi, we find the face of the country very flat; indeed, Delhi, Oude, and Bengal, are the most flat provinces in Hindostan. The surface of Orissa, also north of the river Chumbul, is flat, but to the south of that river, as well as in the north-west, it is hilly. Proceeding to the south, the first lofty land we meet with in Hindostan Proper, is in the Bundelcund district of the province of Allahabad, in the south-west. The southern part of Bihar is also hilly, while the northern division of this province, beyond the Ganges, partakes of the flat character of Bengal and Oude. On the east side of the Dekan, before we arrive at the Ghauts, there is a mountainous ridge, extending from the Godavery to the Mahamuddy; proceeding across the country in a direction nearly due west from this ridge, we enter the province of Berar, the surface of which is for the most part elevated and hilly; the same character applies to the province of Guduwana, Khandish, Hyderabad, Oressa, and the Northern Circars. The south of India consists of table land, or rather an elevated surface considerably broken in the centre, and remarkable for many hills and rocks, the natural strength of which has been greatly augmented by the erection of fortresses on them; the Ghauts on the east and west of this table land, and a flat country between both the chains of Ghauts and the sea. In the province of Malabar, however, there is a chain of low hills, separated from one another, and from the Ghauts, by narrow vallies; in some places these hills rise to the sea coast, but in other parts there is between them and the sea a flat tract, seldom above three miles wide, and in general not so much; near the low hills these plains are the most level.

On the north, Hindostan, in the largest acceptance of the word, is bounded by the Himalaya mountains. These are now known to be superior in elevation to the mountains in South America; their height above the plains of Rooricund being about 27,000 feet: branches spread from them to the south, as far as the borders of Bengal, Oude, and Delhi. The last province is also separated from Northern Hindostan by the Seevalic or Kennaon mountains, which are low compared with those of Himalaya; the principal passes into these mountains from the province of Delhi, is called the Lotidony Pass. The Vendiya mountains, among which lies the Arcadia of India, pass through Bahar, Benares, Allahabad and Malwah, along the north side of the Nerbuddah, nearly to the western coast: to the south of these is a less elevated chain, called the Talia hills. The Ghauts, however, are the most remarkable mountains in India. They are divided into the Eastern and Western; the latter, which are called Sukhian Purbut, or hills of Sukhien, stretch from Cape Comorin to the Tuptee river near Surat, in a line nearly parallel with the sea coast; their general distance from it is 40 miles; in some places 70, and in one part only 6 miles. At the Tuptee, their direction is suddenly changed from north, with a little inclination to the west, to east, running nearly parallel with that river. These Ghauts run through 13 degrees of latitude, being nearly unbroken the whole of their course, except opposite to Paniyam: here there is a valley which extends 14 or 15 miles between the termination of the northern Ghauts and the commencement of the southern Ghauts; through this valley the river Paniyam flows from the Comorin province. In that part of the western Ghauts which runs parallel to the Tuptee, there are several passes from which there is a descent into the province of Khandesh. There are also some passes from the Concan district of the provinces of Bombay through the Ghauts; the principal of which are the Ambah-Ghaut and the Tournia-Ghaut, (for the word Ghaut properly signifies a port or pass.) The mountains near the Ambah-Ghaut rise to a very great height; the pass at Tournia is much more rugged and steep than that of Ambah; and in the middle of it there is a plain of some extent. The principal pass from the Mysore country through the Western Ghaut is Berligea Ghaut, which leads into the maritime province of Canara. As this pass is much frequented for the purpose of conveying grain by means of oxen to the sea-coast, and bringing back salt, the road has been formed with great labour; notwithstanding which, the strength and rapidity of the torrents are such, as frequently to wash away all the smaller and softer parts, and to leave single rocks four or five feet
in diameter, in the centre of the road, not above two feet saunter. This pass is often travelled at night by torch light. The western Ghauts, especially about the latitude of 12°, are covered with a rich mould, on which various kinds of forest trees grow with great luxuriance. Their height has not been measured, but it is supposed to be about 5000 feet. The eastern Ghauts do not extend so far to the south as the western, beginning only a little to the north of the Cavery, about the latitude of 11° 20'. Their line is nearly straight and is uninterrupted as far as the banks of the Krishnabah, in latitude 16°. At Madras their height is greatest. It is estimated to be 3000 feet; as Bangalore, in latitude 10° 37', and longitude 77 46' east, which lies within the Ghauts, was ascertained by baromtrical observations to be 2901 feet above Madras. To the south of the Nerbuddah, all the rivers flow eastward, as the eastern Ghauts are not so high as the western; they are also less abrupt in their elevation; and their general character is less fertile and pleasing, in the most part exhibiting naked, sun-burnt, and rocky peaks. To enter the Mysore country, there are several passes, the principal of which are those of Mugglee, Palole, Amboo, Chagamna, Attoon, and Nautoor. The last was always considered one of great importance, as it commands the main road leading to the upper Carnatic from the Valley of Veniambody, in the Barramahl, which is the most direct route to and from the Mysore. This pass has been levelled and widened since the British gained possession of the province. The other passes all centre in the Pallosand pass; hence, though Hyder and Tippoo possessed the advantage of all these routes when they attacked the low country, they had but one entrance at this part into the Mysore to defend.

From the general description which has been given of the surface of the country, it will naturally be expected that the most numerous and extensive plains must be sought for in Hindostan Proper. Indeed, the whole country through which the Ganges flows, from the Scenery mountains to the sea, is one vast plain. There is also a plain stretching from Surbind to the city of Delhi, in a N. W. direction, a distance of 155 miles. This plain contains the towns of Panniput and Carnawal, and it is celebrated as the scene of two great battles, one in A. D. 1522 between the Emperor Baber and the Patan Sultan Lodi; and the other in 1761, between the Maharrattas and the Mohomedan army commanded by Abdali. Across the eastern entrance of the pass of Paniany, already described, there is an elevated plain 60 miles in extent, which rises suddenly from the level of the surrounding country, resembling an extensive terrace. It is bounded on the west by a forest. There are similar elevated plains in Bengal, and in the Bundelca country, south of the Ganges, near the Soolagh with Ghast. From the summit of the Minaret in front of the Mausoleum of Achar, at Secunder, 6 miles to the north of Agra, there is an extensive plain, 30 miles in a direct line, filled with the ruins of ancient grandeur.

Of the Sandy Desert mentioned by Herodotus, our knowledge is but imperfect. Cutch lies to the south of it; Guzerat to the east; Sind to the west, and Ajmeer to the north. These are the limits generally assigned to it; but, according to Major Rennell, it extends from the sea to the Punjab country. In this extent, however, he probably comprehends the Rann, a large salt morass, which bounds the western frontiers of the province of Guzerat, and communicates with the Gulf of Cutch, and which in some places seems to adjoin, and in other places to be interpolated with the Sant Desert. The latter is about 650 miles in length, and about 160 miles in the widest part. In some parts of it there are spots of clay mixed with the sand; but, in general, the country is dreadfully bare, desolate, and sterile; and the wells are frequently at the distance of 8 or 10 coss from one another. All over this sandy tract there is scattered jungles, but of stunted growth. The Run, or salt moss, in some places consists of water only a few inches deep; in others it is an impassable swamp; and in others a bank of sterile and loose sand. It is every-where saline. It bounds the north of Cutch, and, including its windings, is supposed to extend several hundred miles. This marsh evidently must have been, at some remote period, covered by the sea, the waters of which are still slowly draining off; but when it was so covered is not known. Legendary tales and songs record the passage of the Run at Malia on the river Muckoo, by Jam Dhamanu, who invaded Guzerat from Sind, about the year A. D. 700. This is evidence of the existence and extent, in this quarter, of the mo- rash at this period.

The only rivers of Hindostan of a very lengthened course, or great volume of water, are those which run through Hindostan Proper, the Indus and the Ganges, with their respective tributary streams. The Indus enters Hindostan about the latitude of 33° 15'. Here it is an inconsiderable stream, but its breadth and volume of water is much increased by the junction of the Attock, which, as flowing into it from the west, requires no farther notice under this article. The Indus pursues its course through Hindostan to the beginning of its Delta, about 170 miles from the sea, nearly in a straight line south by west. Of its two branches which form the Delta, the westernmost is the largest; and this, after flowing nearly 50 miles to the south-west, again divides into two other streams, which, as they approach the sea, are subdivided into numerous creeks. The whole course of this river, from its entrance into Hindostan, is about 900 miles; but the tide does not flow up more than 60 or 65 miles. At Tatta, about 130 miles, by the course of the river, from the sea, the Indus is very shallow; about five miles below this town, the greatest depth is four, and the current depth only two fathoms; the breadth here is about a mile. The land floods, occasioned by the melting of the snow, begin about the middle of July, and do not subside till the end of August. Notwithstanding the tide flows but a short way up this river, on account of the shallowness of its stream, yet it enters the mouths of the different branches with extraordinary violence and velocity, so as to carry up the current frequently, in some places, at the rate of four miles an hour. The tributary rivers of the Indus chiefly flow into it in the northern half of its course, in the province of Multan, forming the Punjab, or country of rivers. These rivers, the Jhylum, or Behut, the Chunnaub, the Itavy, the Beyah, and the Sutlej, all rise nearly in the same place, at the foot of the Himalaya mountains. The Jhylum, the Hydaspes of the Greeks, after crossing the great road leading from Lahore to Attock, and flowing along the eastern side of the Joud mountains in the province of Ajmeer, unites with the Chunnaub, near Jehangir, about 60 miles above Multan. Its whole course is about 400 miles. It is the most westerly of the streams that flow through the Punjab into the Indus. The Chunnaub, the Acesines of the Greeks, is nowhere, after it enters the Punjab, more than 55 miles
from the Jiyllum; about 28 miles above the city of Multan, it flows into the Ravey; the length of its course is about 420 miles. The Ravey enters the plains of Lahore near Shashpoor; its course is south-west till it passes the city of Lahore, above which it is 120 yards broad, and very rapid. After its junction with the united streams of the Chunaub and Jiyllum, its breadth for a little way is upwards of a mile; but it soon contracts into a rapid stream not more than 350 yards across. It falls into the Indus 20 miles below Multan, bringing a volume of water nearly equal to that of the Indus itself. Its whole course is about 500 miles.

The course of the Beyah, for the first 200 miles, is directly south; it afterwards flows to the west; it unites with the Sutlege about 300 miles from the sea; their junction, however, formerly took place much lower, where there is still a small canal called the Oldbedyke river. The whole length of its course is about 350 miles. The Sutlege is the most eastern of the rivers of the Punjab; it enters Hindostan at Bellegpoor in the province of Delhi. Before it is joined by the Beyah, it is a very considerable stream; after their junction, they lose their respective appellations, and take the name of Kirah, the Hyphasis of the Greeks. About 20 miles below their junction they again separate, and four streams are formed. Near Multan they unite again, and fall into the Indus about 50 miles below that place; it is navigable 200 miles above the junction; its whole course is about 600 miles. These five rivers of the Punjab increase the breadth and depth of the Indus so much, that there is water sufficient for vessels of nearly 200 tons burden, from the Gulf of Cutch to Lahore, a distance of 760 geographical miles; these vessels, however, are flat-bottomed. See INDUS.

The Ganges rises on the southern side of the Himalaya Mountains, and enters the plains of Hindostan at Hardwar, in the province of Delhi, latitude 29° 57', longitude 78° 2'. Its course is nearly straight till it passes Allahabad, when it becomes more winding, and its bed deeper and broader. After receiving the tributary streams of Bengal and Bahar, some of which are equal in volume to the Rhine, the channel attains its full breadth, which is commonly about three fourths of a mile, when the river is at its lowest. Its depth, at this time, is 30 feet for an extent of 500 miles, before it reaches the sea. Of the different branches into which this river is divided before it enters the gulf of Bengal, the westernmost, called the Hooghly, and the most eastern, which receives the Brahmapootra, are the widest and most important. The Hooghly is the only branch that is commonly navigated by ships. The whole course of the Ganges is about 2500 miles. For a fuller account of this river, see the article GANGES.

The first large river that joins the Ganges after it enters Hindostan Proper, is the Jumnah: Its source is supposed to be farther to the north-west than that of the Ganges. A little before it enters Hindostan Proper, (which it does in the province of Delhi,) the two rivers are only 40 miles distant from each other. After its entrance into Hindostan, its course is nearly parallel with that of the Ganges, at the distance of from 50 to 75 miles. These rivers unite at Allahabad. Its whole course is about 750 miles, on the west side of the Ganges. Ten miles below Etawah, a town in the province of Agra, the Jumnah is joined by the Chumble, which rises near the source of the Nerbuddah in the province of Malwah. Its course is north-easterly; its whole length is 440 miles. It constitutes the boundary between the British possessions in Hindostan Proper on the south, and those of Scindiah. The largest rivers that flow into the Ganges from Bengal and Bahar are the Goggrah, the Soane, and the Cosa. The first is composed of the waters of the Goggrah and the Saregu, which unite at Swargadwara. They afterwards flow through the province of Oude, and unite with the Ganges in Bahar. The course of the Goggrah is nearly parallel to that of the Ganges on the east side. The Soane rises near the Nerbuddah, on the east side of the table land of Amurcunt. Its direction is at first due north; it afterwards turns to the north-east, and joins the Ganges in the province of Bahar. Its whole course is about 500 miles. The course of the Cosa, which rises in the Himalaya mountains, is at first S. E.; it afterwards winds very much. Its junction with the Ganges takes place 45 miles above Rajemain, in the district of Punjab, in the province of Bengal. Formerly these rivers united at Rajemain: its course is about 400 miles. The Brahmapootra, which afterwards forms the great eastern branch of the Ganges, is supposed to rise very near that river. Its course for a considerable way is eastward, and at one place it reaches within 220 miles of the most western province of China. It then very abruptly turns to the west, through Assam, on the north-east of Bengal,—a country remarkable for the number and magnitude of its rivers, most of which flow into the Brahmapootra. It enters Bengal near Ranjamattey. Its course is now west, and afterwards south, in the Decan district of that province, where it is joined by the Megna. The Ganges and the Brahmapootra unite below Lucksipoor. The whole course of this river, as far as it is known, is about 1650 miles. It flows 400 miles through Bengal. Though the Ganges and it rise near each other, yet at one part of their course they are 1200 miles distant.

The rivers in the Decan, or central division of Hindostan, are the Nerbuddah and the Tuptee on the west, the Drav and the Subunreka, the Mahanada, and the Godavery can. on the east. The Nerbuddah's course has been already noticed; but while the Soane flows to the north-west, the Nerbuddah takes nearly an opposite course, flowing almost due west. It has fewer windings than most Indian rivers. After passing through part of the provinces of Gundernwa, Khandeish, Malwah, and Guzerat, it joins the sea 25 miles below Baroacht. Its whole course is about 750 miles. The Tuptee, or Surat river, rises in the mountains which bound the province of Berar on the north. Its direction is westerly, through Khandeish and Guzerat; and, after a course of about 400 miles, it falls into the sea about 20 miles below Surat. The Subunreka rises in the southern extremity of the province of Bahar. Its course is to the south-east for 250 miles, when it falls into the Bay of Bengal, about 30 miles to the west of the Hooghly mouth of the Ganges. This river is by some considered as the north-east boundary of Hindostan Proper. The Mahanada rises in the hilly country of Gundernwa; its course is very winding. In the district of Cuttaek, in the province of Orissa, it receives several streams, one of which afterwards separates from it. The Mahanada then directs its course to the bay of Coojung, where it falls into the Gulf of Bengal. Its whole course
Statistics. 63

is 530 miles. The Godavery rises in the Western Ghauts at Trembuch Nassor, about 70 miles to the north-east of Bombay. Its course is at first due east, through Arungabad and Telligna; it afterwards turns to the south-east. At Rajamundry, in the Northern Circars, it divides into several branches, which form a fertile Delta, and several harbours for small vessels. Its whole course is about 850 miles. About 90 miles from its mouth it is joined by the Bajhunga.

To the south of the Tuptee, the course of all the rivers is to the east, in consequence of the superior elevation of the Western Ghauts. The few rivulets that flow into the western sea descend so abruptly from the mountains, that they have not time to collect into streams of any magnitude. Those on the eastern side are mostly choked with sand-banks, thrown up by a violent surf across their mouths. Some of these, however, require notice.

The Krishniah rises in the Western Ghauts, not more than 50 miles from the west coast of India. Its direction is to the south-west till it reaches Merseitch in the province of Bejapoor. Here it is joined by a number of streams from the Ghauts, united under the common name of Warnah. Its course is now to the east, when its volume is again increased by several rivers, the principal of which are the Malpurba and Toombuddra. It forms a delta near Manilipatam, after a course of nearly 650 miles. It equals, if it does not surpass, any other Indian river, in the fertility which it creates during its course; watering, and of course fertilizing the provinces of Bejapoor, Beder, Hyderabad, &c. To the south of the Krishniah, is the Pannar, the Palur, and the Cavery. The Pannar is said to spring among the hills of Nundydroog in the Mysore. Its course is northerly till it reaches Goaity, in the Balaghat ceded districts, when it changes to the south-east, and afterwards to the east. It falls into the sea at Gangapatnam in the Carnatic, 108 miles to the north of Madras. The Palur also springs from the hills of Nundydroog, but its course is to the south. After flowing 290 miles through the Mysore and Carnatic, it falls into the sea at Sertarum. The Cavery has its source in the Coorg country, a district among the Western Ghauts, but it is of no magnitude till it quite it. Near Seringapatam it forms an island; and opposite to Trichinopoly in the Carnatic, it again separates into two branches, which surround the island of Seringham. The northern branch is named the Cologoorn, the southern retains the name of Cavery. About 15 miles farther to the east, these branches approach each other; and an immense mound is formed in order to prevent the Cavery from falling into the Cologoon, the bed of which is 20 feet lower. The Cologoon falls into the sea near Negiapatam, and the Cavery at Tanjore. These rivers form a wider delta than any other river in this part of India: their whole course is about 800 miles. In North Coimbatoor, near Sivana Samodra, an island formed by the Cavery, there is a cataract, the fall of which is about 150 feet; another near the upper end of the island; and the ruins of a grand bridge across the Cavery, which was formed of blocks of granite 20 feet in diameter, 20 feet long; when entire, the bridge was 300 yards in length.

There are but few lakes in Hindostan. The Chilka lake divides the northern Circars from the Cuttack district of Orissa. It is about 55 miles long, and eight broad. Towards the east and south, it is bounded by a narrow sand, very plain and flat, and about a mile in breadth, and on the north-west by a chain of mountains.

The water is salt, as it has a communication with the sea by a very narrow and deep outlet; and, indeed, evidently has been formed by the sea breaking over the flat sandy shore. This lake receives one of the branches of the Mahanada. It contains several islands, which are inhabited. Between the Krishniah and Godavery, in the lower part of their course, there is an extensive tract of flat and rich country, evidently alluvial, and formed by these rivers. It is about 160 miles in length along the sea coast, and from 40 to 50 wide. About half way between the two rivers, there is a hollow of considerable extent in this alluvial soil, in the lowest parts of which there is a lake at all seasons. The whole extent of this hollow ground is 47 miles from west to east, and 14 from north to south. During the rainy season, the whole is covered with water, except 60 or 70 very small eminences, on which the inhabitants take refuge. This is the Coloor lake. Between it and the Godavery and the Krishniah, there are traces of a channel, formed by the natives either to drain the lake, or to irrigate and improve the adjacent lands. The latter purpose has indeed been effected by various other channels. The lake of Pulicat, on the coast of the Carnatic, is about 38 miles from north to south, and 11 miles in its broadest parts. Its water is salt, as it communicates with the sea by several narrow channels; and it evidently owes its origin to the same cause which produced the Chilka lakes. There are several large islands in it. The lake of Onore, in North Canara, reaches nearly to the Ghauts. As it is in fact a large basin, it is almost salt during the dry season; but when the rains bring down the torrents from the mountains, its waters become fresh. In the northern parts of Hindostan there are few lakes, especially in the vicinity of the Ganges and the Indus. There are also two lakes close under the walls of Ajmeer; the most northern is six miles in circumference, and very deep.

The greater part of Hindostan Proper is so much intersected by navigable rivers, that canals seem scarcely necessary; while, in the Decan, and the south of India, the surface is in general so very uneven, that they are almost impracticable. Nevertheless, this mode of internal communication was formerly not neglected in Hindostan Proper, though the canals were rather intended and used for the purpose of watering the country, than of conveying goods. The most celebrated were those made in the reign of Firoze II. It is doubtful whether they were ever completed; if they were they would have united the Indus and the Ganges: for one of them was drawn from the Jamniah, near the northern hills, to the city of Hisar; and the object of the other was to form a water communication between the Satlej and the same town. The first canal, which seems to have been completed, was 116 geographical miles in length. It was repaired and first used to Delhi, in 1620, by Shah Jehan; thus making its whole length 174 geographical miles. There is no precise or clear information respecting the part of the Satlej from which the other canal was drawn. It is said to have been 100 miles long. Besides these main canals, there were several branches which united them in different parts, and in different directions. The design of Firoze was to fertilize a vast tract of land very dry and sterile, and also to facilitate and increase inland navigation. In 1810, the British government completed and repaired the canal to Delhi, which, during the convulsions of the Mogul-empire, had been almost wholly choked up. From Shahpoore, where the Ravey enters the plains, a canal was drawn from this river to

Rivers of the south of India.
Lahore, about 80 miles in length; the object was to supply the city with water during the dry season. For the same purpose three other canals were drawn from the Ummern, near Shaipoor, to the south and east of Lahore. In the year 1808, a canal was made from the Black-town of Madras to the river Ennore. Its length is 10,560 yards; its greatest breadth at the top 40 feet; and its greatest depth 12 feet. By means of this canal, boats convey charcoal and fire-wood, the produce of the high land behind Pulicat, to Madras. The rivers of Bhavani and the Panam, which approach within about 1800 yards of each other near Fort St. David, are joined by a canal, which runs nearly parallel to the sea, at the distance of about 1000 yards.

The eastern and western coasts of India differ in a very striking manner. The Malabar, or western coast, is high and bold, and possesses a few excellent small harbours, formed by insulated rocks and promontories. The Coromandel, or eastern coast, is low, sandy, and full of shoals and banks, without a port of any kind; the entrance to its small rivers being blocked up by the sand thrown in by the dreadful and dangerous surf, which beats against it at all seasons. Having given this general description of the two coasts, we shall commence a more detailed account of them at the north-west extremity of the western coast.

Cape Monze, which lies in the latitude of 24° 55', and in the longitude of 69° 40', is considered as the commencement of the coast of Hindostan in this quarter. The bay of Corachin lies between this cape and the Indus. It admits vessels of 300 or 400 ton during the rainy season; the tide rises 12 feet. On the eastern side of the bay are six rocky islets. From Cape Monze to the Gulf of Cutch, it is called the coast of Sind. The Gulf of Cutch runs far inland towards the east. The upper part is full of shoals, and is bounded by a low narrow plain, always overflowed during the rainy season. It is said to have a communication with the Run, already described. On the south shore of this gulf, the coast of Guzerat begins. Between it and the Gulf of Cambay, it is rather high. The Gulf of Cambay is bounded by the coast of Guzerat on the west, and by that of Surat on the east. It runs nearly 150 miles inland. Near to Cambay, which stands near the upper part of the Gulf, the tides run with extreme rapidity, nearly at the rate of six miles an hour: at high water rise 40 feet, and at low water leave the Gulf dry, even for seven leagues below the town. Fifteen miles to the east of this town, the breadth of the Gulf is only six miles. It is here also completely dry at ebb tide; but the bottom is covered with mud and quicksands, so as to render a passage across without a guide extremely dangerous. Both in the Gulfs of Cutch and Cambay, the bore or rush of the tide is nearly as rapid as that at the mouth of the Indus and Ganges. The depth of water in the Gulf of Cambay, is supposed to have been gradually diminishing for upwards of two hundred years. The river Jumnaier runs into the east side of the Gulf, to the south of Cambay. On it stands a town of the same name. The Nabudah also falls into this part of the Gulf. On it stands the town of Baraoch. As we approach further to the south, to the coast of Surat, the coast becomes more level. The first seaport that occurs is Surat, on the left bank of the Turas, about six leagues from the sea. This river, however, is so shallow at the town, that large vessels are obliged to anchor at its mouth. During the south-west monsoon this anchorage is dangerous; but it is safe and commodious while the north-east and north-west winds blow. The coast between Surat and Cape St John continues so very low, that, during the prevalence of the south-west monsoon and high tides, it is inundated. There are several small rivers in this tract. From this cape to Bombay, a reef, lying three leagues off, stretches along. Bassein, a port in the province of Aurungabad, lies on a narrow strait, or rivulet, which separates it from the island of Salsette. Across the mouth of this there is a bar of sand, so that only small vessels can enter. Salsette, 18 miles long and 14 broad, was formerly divided from Bombay by a strait six miles long, and about 200 yards across, which was occasionally fordable; but these islands are now united by a causeway. Bombay is about 10 miles long, with an average breadth of three. This island, with Salsette, Caranga, and Elephanta, forms a most commodious harbour. The tides rise higher here than in any harbour possessed by the English in their Indian settlements. The usual height is 14 feet, but they sometimes rise to 17. Advantage has been taken of this circumstance, to construct docks large enough to build a 74 gun-ship. We now enter on the coast of Cooncan, on which the first object of importance is a rocky promontory, joined to the continent by a narrow neck of sand, about one mile long and a quarter of a mile broad. On this promontory stands Gheriah, formerly the capital of the celebrated pirate Angria. A river of some magnitude runs from the Ghauts into the sea, on the north of this promontory. About 30 miles to the south of Gheriah, lies Melunday or Malwan island, the principal abode of the pirates who at present frequent this coast. To the south of it, 4 leagues off the coast of Bejapoor, lie a cluster of rocks, called the Vingoria, or burnt rocks. On the left bank of a navigable river, and about seven miles from the sea, stands the town of Goa. There is here a good bay, bounded on the south by the peninsula of Marmagon. From Goa to Cape Rama the coast is low, with a beach of sand. Near this cape is Salsette river, a branch of which communicates with the river of Goa, thus making an island of the scite of that town. There are few coasts so much broken into small bays and harbours, and at the same time retaining so strait a general outline, as the coast between Bombay and Goa, a distance of nearly 220 geographical miles.

After passing Cape Iltams, the coast of Canara begins. At Fort Carwar there is an inlet of the sea, Canara, with a wide and deep, but intricate channel. To the south of this is the island of Anjediva, about a mile in circumference, and two from the shore. It lies before a bay, which is formed by two promontories, so lofty, that they afford some shelter to ships, even during the S. W. monsoon. Meerjanur, a river of the same size, which, in the month of February, seven miles from the sea, is 700 yards across, affords the most convenient wooding and watering place on the coast of Malabar. The Lagoon of Ouore, already described, succeeds in latitude 14° 18'. On the north entrance of this lagoon is an island that has been fortified by the British. To the south of this there are several promontories, forming bays tolerably well sheltered. There are also several small islands, of which the most remarkable are Hug island and Pigeon island. Mangalore, in South Canara, in latitude 13° 49', is situated on a peninsula, which stretches into a small salt lagoon that is separated from the sea by a sand beach. Across this beach there was formerly an opening capable of receiving large ships; but at present this channel has become so shallow, as to admit only vessels drawing less than 10 feet. There is another channel with still less water.
Twenty-five miles east by south from Mangalore, stands Cumly, on a high point of land between two rivers, which run into a salt water lake, that is also divided from the sea by a narrow sand bank. In the rainy season both the rivers and the lake are fresh. From Cumly for several leagues to the south, the coast is lined by a range of salt water lakes, which, however, are of little use to navigation, in consequence of the sand banks which lie between them and the sea.

The coast of Malabar begins at the river Chandra, in latitude 12° 27'. This coast is much indented by inlets of the sea and salt lagoons, lying within a chain of sandy and narrow islands. These inlets run for a long distance parallel to the coast, and receive the small and rapid streams that descend from the Ghauts. They open to the sea by narrow and shallow channels. The first remarkable spot on the coast of Malabar is Mount Dilla, which is separated from the main land by salt water creeks. The best bay on this part of the coast is formed by a point of land, on which stands the fort that protects the entrance to the town of Cananore. The town itself is situated at the bottom of the bay. Tellicherry, in latitude 11° 44', succeeds; it stands on a small river. The coast here is very low and sandy. At Vadagham, in latitude 11° 35', the series of salt lakes commences, which run without interruption to the south, forming a kind of inland navigation, protected from the sea by a chain of sandy islands. Calicut is situated on a river, navigable by boats, 100 miles up the country; it is the port principally frequented by the Arabs of Muscat. Panjany, 40 miles south-east from Calicut, is situated on the south side of a river, which flows from Animalaya, or Elephant Hill. The entrance of this river, though wide, is so obstructed by a bar, that only the trading boats of the natives can reach the town. The salt lakes, islands, and small ports situated on them, now become numerous; but the first of consequence, to the south of Panjany, is Cochin, which is built on a very low island. The inlet to it is navigable for vessels of considerable burden.

Cape Comorin, the southern extremity of Hindostan, in latitude 7° 57', and longitude 77° 32', is in itself low and level; but, about half a mile to the north of it, there is the mountain of Komari, the southern termination of the Ghauts, the summit of which is said to be 1200 feet above the level of the sea. This is regarded by mariners as the cape.

The south-eastern extremity of Hindostan is occupied by the coast of Tinnevelly. In it are no ports of any moment. On some parts of it the tide rises only two or three feet. Between the island of Ceylon and Point Ramen is the island of Ramissaram, about eleven miles long and six broad. It is low and sandy. The strait between it and the main land is about a mile wide; but so obstructed by rocks, and with an entrance from the north so very narrow, that it cannot be navigated, except by very small vessels. This is an island of great sanctity in the opinion of the Hindoos. From Point Calymer to the river Cavery is the coast of Tangree, which is so extremely low and flat, that the first objects seen, in approaching it, are the tops of the cocoa palms. Negapatam, 48 miles to the east of the town of Tangree, in latitude 10° 45', is situated on a small river; but the coast vessels, or ships for refreshments, frequent it. Tranquebar, in latitude 11°, is situated on a small river, across the mouth of which is a bar. The best roadstead on this part of the coast is off the town of Portonovo, in latitude 11° 30'; it is sheltered on the south by a shoal. Pondicherry, on the river Gingie, is a port of little consequence with respect to trade, as the river can only receive small vessels even during the rainy season. Its roadstead, however, is not so dangerous as that of Madras; and landing may occasionally be accomplished in ships' boats. To the north of Sadas, and about 38 miles south by west from Madras, the coast seems to have been encroached upon by the sea, to a considerable extent. About 100 yards from the sea, there is a high rock, covered with Hindoo sculpture and imagery. There are also other rocks washed by the sea, which, by the inscriptions on them, appear to have been formed by a considerable distance from it. According to the traditions of the brahmins, a large city, called Mahabalipuram, or the city of the Great Ball, stood here in very remote times; and the surf is said still to break over its ruins. Madras, in latitude 13° 5', and longitude 80° 26', lies on a coast, where a rapid current runs, and on which a dreadful surf breaks, even when the weather is the most moderate; the shore here is perfectly steep. Hence the roadstead of Madras is the worst in India; the most dangerous season to remain in it, is from the beginning of October to the end of December; large ships generally anchor about two miles from the shore. When the surface is unusually high, catamarans are used to convey passengers from the Manilla boats; the latter are formed of materials that easily yield to the stroke of the waves, and are always employed between the ships in the roads and the shore. In the latitude 15° 30', the coast of the Carnatic terminates, and that of the northern Circars begins. After passing Masulipatam, on a branch of the Krishna, and some other plains of less importance, we arrive at the bay of Coringa, in latitude 16° 42'; into this bay one of the branches of the Godavery falls; a bar of mud lies across its entrance, through which ships must be forced. This is the only place on the east coast of Hindostan where there is smooth water during the south-west monsoon, so that a ship of above 200 tons can be thoroughly re-fitted here by being hove down. A little to the north of Coringa bay, the low coast terminates, and a ridge of high mountains commence, which line the coast to Ganjam in latitude 19° 23'. There is nothing remarkable as we proceed northwards, till we arrive at Point Palmyrac, which forms the entrance into the Bay of Balasore on the south. A reef extends nearly 10 miles to the ENE. of this point. There is but little depth of water in the Bay of Balasore; in some places the water leaves the shore for half a mile out at low tide; and even at the distance of three leagues there is not more than seven or eight fathoms: this arises from the immense quantity of mud and sand carried out by the Ganges. The shores of the bay are intersected by several small streams, some of which are navigable. The town of Balasore stands on the Hoorece Hillaun river, where the tide commonly rises eight feet: at high water vessels of 100 tons burden can cross the bar.

The coast of Bengal commences at the town of Pifley on the Subunreeka river, about 22 miles N. E. from Balasore, in latitude 21° 42'. This was formerly a port of considerable trade, but it is now little frequented, in consequence of the flood having formed a dangerous bar across the mouth of the river, as well as washed away a great part of the town itself. The course of the Ganges to the sea has been already described. Across the entrance of the Hoogly, or western branch of it, there are several bars, which render the navigation difficult and dangerous, particularly two, called the eastern and western sea reefs. The whole of the coast
Bay of Bengal.

The coast which we have described, from Cape Comorin to Chittagong, forms the western side, and the bottom of the Bay of Bengal. The western side stretches from Cape Comorin to Balasore; that is, from latitude 7° 57' to latitude 21° 34', and the bottom of the bay from Balasore to Chittagong, or 4° 53' difference of longitude. The depth of water on the western side is very great, at a comparatively short distance from the shore, there being no soundings about 30 miles off. At the bottom of the bay, however, the sea is shallow.

The British and their allies are in possession of all the sea coast of Hindostan, except that part of it which stretches from the small islands to the south of Bombay, in latitude 18° 42', to the small islands about 17 miles north by west from Goa, in latitude 13° 50'. This part of the coast is principally occupied by pirates. The sea coast from the Gulf of Cambay to the river Indus is also occupied principally by pirates.

CHAP. III.

Natural History.—Botany.—Zoology.—Mineralogy.—Climate.—Soil.

To discuss fully the natural history of India, and particularly those branches of it which relate to botany and zoology, would require much more ample space than can possibly be allotted to this article. It will be necessary to be brief and minute in the description of the botany and zoology of India. The mineralogy, not presenting either ample or such characteristic materials, will be treated of with comparatively less brevity. With regard to its botany, we shall select for notices and description those plants chiefly which are used for the purposes of medicine, food, the arts, or domestic purposes, or which are distinguished by the beauty and elegance of their form or flowers.

Acacia. 

Acacia catechu, Catechu, called in the province of Bar Coor, grows in abundance in most of the mountainous districts of Hindostan. The extract from it, which is called cut by the natives of Hindostan, cùth by the English, and by different authors khánt, cut, catechu, &c. is brought to England both from Bengal and Bombay. According to the analysis of Sir Humphry Davy, the variety which comes from Bombay contains 109 of tannin, 68 of extractive matter, 13 of mucilage, and 10 of earths, and other impurities in 100 parts; and the variety from Bengal, 97 of tannin, 75 of extract, 16 of mucilage, and 15 of impurities. The name catechu, under which it is now more generally known, is derived from two oriental words, cātē a tree, and chu juice. This species of acacia seldom exceeds 12 feet in height. The catechu is extracted from the inner wood. Acacia Arborea, the Babul tree of the Hindoos, grows in great abundance all over the Deccan. Its flower is rather beautiful, consisting of a bright yellow ball, which is very sweet scented. The wood is hard and tough, and is considered to make the best wheels and axletrees of any in India. Its bark is used for tanning. The gum drawn from it resembles in its qualities gum arabic so nearly, that it is used instead of it for all purposes in Hindostan. In Guzerat, especially in the wastes, the Babul tree is very common. The poor inhabitants of this province use its gum as food. It is planted in some places to protect the villages and farm-yards. It was formerly supposed that catechu was extracted from the nut of the areca; but this does not appear to be correct. The areca, however, which is a species of palm, is cultivated nearly over the whole of India for its nuts, which are used by the natives, mixed with the leaves of the betel, pepper, and a little quicklime or shunnel, in the same manner as tobacco is used by Europeans. This tree is seldom met with in a wild state. It however grows spontaneously on all the hills in South Concar, and in North Canada. None of it grows above the Ghat. In Malabar there grows, or is prepared, a sort of red areca, which is used in dying. Besides the areca, there are a great variety of other trees of the palm kind in India. The cocoa-nut tree is found everywhere, especially on the coasts of Malabar and Coromandel, as it requires a low sandy soil. On the higher grounds, the cocoa-nut tree begins to yield its fruit when seven or eight years old. How long it lives cannot be ascertained; but it undoubtedly attains a very great age. If the trees are of good quality and young, they will supply 100 nuts annually, which are ripe at all seasons of the year. But the benefits which the natives derive from the tree are by no means confined to its nuts. It supplies oil for the lamp; coir cables are made from the fibrous covering of the nut; toddy or arrack is supplied by the juice of this and several other species of palm trees; and though the British confound all the kinds of arrack, the natives have distinct names for each kind of juice.

Graham's Residence in India, p. 26. Properly speaking, the arrack is the juice or toddy prepared by distillation; and the apparatus employed for this purpose is very simple. Besides the toddy, a fermented juice, jaggery, or an inspissated juice, is made from the palmyra, and other species of palm. In Bengal, the toddy and jaggery produced from the wild date are the most esteemed; but in the Jaggire district of the Carnatic, where the palmyra thrives extremely well, and requires little care or attention, the toddy and jaggery from it are considered the best. The leaves of the cocoa-nut tree are used to cover the houses, and out of two of them plaited together, the peasants form a kind of cloak, which defends them from the rain while working in the fields.

From the smaller fan palm toddy is also made: its Fan palm.
leaves, which are broad, are used for writing on and for thatching. The palmyn or brab is another species, the leaves of which are also used for thatching, and for fuel. The largest species of this kind of trees is the greater fan palm, which is very abundant in the Payenghaut, or lower Carnatic; it is said that each leaf of this tree is capable of covering a dozen men, and that two or three of them are sufficient to roof a cottage. The wood of all these species of palms is excellent for water pipes and rafters. The most beautiful of the palm trees which grows in India is the sago palm, but this is by no means so common as any of the other species. We have by no means enumerated all the uses of the trees of the palm kind. F. P. Bortolomeo says, that he has reckoned up forty different properties that the real palm tree possesses, which are all useful to man.

**Eleocharis cardamomum**, or the cardamon plant, grows in the mountains above Cochin and Calicut, chiefly in shady places on their declivities and in the valleys. The district of Wyniard, situated on the summit of the western Ghauts, about the 12th degree of latitude, produces the best cardamons in India. There are also found at the bottom of the Ghauts, at Maleatur, cardamom paxl, yajap, &c. The tree rises about 12 feet in height. The cardamons, or seeds, are brought chiefly in the ships from Bengal, in cases containing about 120 lbs. weight.

Pepper. It has been long known that the long-pepper tree, *Piper longum*, was a native of India, particularly of the Malabar and Bengal provinces; but it is only within these thirty years that the discovery of the black pepper plant (*Piper nigrum*) was made in the district of Bampa, in the northern Circars. Dr. Roxburgh began the cultivation of it in this province in 1767. It is also much cultivated in the province of Malabar, and constitutes one of their principal articles of export. One thousand plants yield from 500 to 1000 lbs. of pepper. The plant climbs like a vine; is from 8 to 12 feet in length; and is generally supported by the Mooley wood tree, *Erythrina corallodendron*. Nearly all the forests in the neighbourhood of Yellapura, a town above the western Ghauts, produce pepper spontaneously.

Betel tree. *Piper betel*, the leaves of which are called betel, is found to succeed best in India on such grounds as can be irrigated at particular seasons of the year. On that tract of land along the banks of the Megrn, the river which bounds the Tipparah district of Bengal on the west, particularly between Daoudeauny and Luckpoor, the *P. betel* is of excellent quality: the produce of this tract is so highly esteemed by the natives of the Birman empire, that they make regular contracts annually for the coming crop; it is nearly all bought up by them for ready money. The general use of it, along with the *cate* and *chunum*, has been already mentioned; the leaves of the betel inclose the cate and chunum.

**Medicinal plants.**

*Cinnamon*, Zeladony, the root of which is sometimes used in medicine as a stomachic; grows in sandy open places in Malabar, where it is called *acai* by the Brahmins. *Dolichos proiria*, grows in Bengal, where it is called *okia*, the plant which produces the gum ammoniac. *Hercules, gummiferum*, is also a native of the East Indies. The *Laurus calis*, which in some respects, but in a very inferior degree, supplies the place of cinnamon in medicine, and for domestic purposes, is a native of Malabar, and frequently called Malabar cinnamon. There are two species of *Pierococcus* found in India. The *P. draco*, which supplies the dragon tree resin, commonly called *dragon's blood*; and the *P. Santalum*, which supplies the red sanders wood; the former is used in medicine, the latter as a colouring matter. *P. Draco* rises to 30 feet high. *P. Santalum* is a native of the mountains of India; it was first discovered there by König. This tree thrives best on a strong soil, and is found in the greatest abundance, as well as of the best quality, in the Mysore, above the western Ghauts. About 20 miles to the south of Periapatam, there is a tract of land, on which an immense quantity of sanders wood is grown; it is fit to cut in about ten years: the sandal is merely the heart of the wood, and in order to obtain this, it is usual to cut the tree into pieces, and bury them in dry ground for a month or two, and this time, the outer wood is eaten by the white ants, but they do not touch the heart: the smallest pieces are generally brought up by the Arabsians, who distil an essential oil from them; the Chinese buy the largest, and the Indians use those of middle size. In the neighbourhood of Periapatam, there is about 2000 weight produced annually. Tellicherry, on the Malabar coast, is the great mart for the Mysore sandal wood; but in the province of Malabar it is scarcely met with, and what there is, is destitute of fragrance. *The Sutatinia felifsiga*, which supplies an astringent and tonic bark, is a native of the East Indies, growing among the mountains of the Rajahmundry Circar; the natives use it for the cure of intermittents. The *Timarinus indica*, tamarind tree of India, produces tamarinds of a darker colour, and drier than those from the West Indies; the pods also are nearly twice as long. The ginger plant grows in most parts of the Malabar coast where the sea-water cannot penetrate; it is called *ai* by the Brahmins.

The Bamboo trees are very common, and very useful. Bamboo in India; scarcely any tree equals them for rapidity of growth, as in the short space of five months they rise to the height of 20 yards, with a circumference of eight inches; its greatest height is completed during its first year; and during the second, it acquires those properties of hardness and elasticity, which compoundly or singly renders its wood so extremely useful for a variety of purposes. A single acre of Bamboo, if they are situated in a proper soil, and care is taken of them, produces more wood than ten acres of any other tree. The best bamboos used for palanquins grow near the summit of the rocks in the pergunmals of Telcan and Hindole, in the province of Orissa. They spring up in July, at which time the stringent shoots are fastened to stakes driven into the ground, in order to train them up to that form which will render them most useful for palanquins. As soon as the dry season begins, their tops are cut off; for, if they were to stand longer, they would become too weak to support a palanquin, in consequence of the increase of the hollow part, and the wood growing thinner. In some places, they are used for the purposes of defence and protection, being planted on the banks of the country fastnesses, on account of their thorns, which are three inches long, and very strong and sharp. In the dry season, however, they can afford little protection, as they are very inflammable. In the neighbourhood of Goonnr, at the north-west extremity of the northern Circars, the forests are almost entirely composed of bamboo; and as, besides their thorns, they grow closer and resist the axe better than any other tree, the inhabitants formerly trusted entirely to their forests of bamboo, binding and intertwining them so
Teak.

The qualities and uses of the teak tree seem to have been little known or appreciated in Britain till near the close of the last century. This valuable tree is found almost exclusively in India, along the western side of the Ghaut mountains, and other contiguous ranges of hills, particularly on the north and north-east of Bassein. On the east side of India, the forests of Rajamundry, which stretch from the hills on the banks of the Godavery to Pootoonshah, contain abundance of these trees; and this is the only district in the east which furnishes this valuable timber. In North Canara they grow in considerable quantities. In the year 1800, the number of teak trees cut down annually in this district, amounted to 3000. In the province of Malabar it grows mostly about Manarghat, in the district of Paluckeenderry. From this district it is computed that about 45,000 cubic feet of this timber might be procured annually; and on the hills above Darugnoda, which might supply from 2000 to 3000 trees every year. The teak is also found at a very considerable height up the Ghauts, but here it is of an inferior size.

The banyan tree must not be forgotten in this sketch of Indian botany. The characteristics of this tree are well known. In Hindostan there are two of wonderful size. That which is described by Milton in his Paradise Lost, stands on an island in the Neruddah, within a few miles of Baraoche. It is said by the natives to be 2000 years old, and is supposed to be the largest in the world, its shade being capable of sheltering 7000 persons. It must, however, have been considerably larger than it is at present, for part of its roots have been swept away, along with the banks of the river, by the floods. It still measures nearly 2000 feet in circumference, even if those branches alone which have taken root are included; and the area which it covers must be considerably larger, if the hanging branches are included. Of the smaller branches there are upwards of 3000; and of those which are larger, and have in fact become trunks, there are 330, most of which exceed in circumference most English trees. The other remarkable banyan tree grows in the Sarun district of the province of Bahar, not far from the town of Manila. The following are the dimensions of it. Its diameter is from 363 to 375 feet; the circumference of its shadow at noon, 1116 feet; the circumference of the several stems, which amount to between 50 and 60, is 921 feet.

There are several trees and shrubs which produce oil, besides the cocoa-nut tree. In the vicinity of Belihore, in North Canara, the Calophyllum inophyllum grows in abundance. It is a lofty tree, frequently 50 feet in height, and 12 in circumference. From the seed of it, the common lamp oil of this part of India is extracted. It is also esteemed for the elegance of its shade, and the sweetness of its blossoms. The Ricinus communis, common ricinus, or Palma Christi, is cultivated in the Mysore; the castor oil which it produces is used for the lamp, and given to the female females, for the purpose of increasing the quantity of their milk, as well as applied to medical purposes. This species of ricinus is also cultivated in the province of Bengal, and in other parts of Hindostan. On the Almooch hills in northern Hindostan, there grows a tree called by the Hindus Phutwarrah. Its usual height is 50 feet, and its circumference six: from the kernels of the fruit a fat-like substance is extracted. There are only a few places where any species of the pine grows. It is found, however, in considerable abundance in the mountainous district of the province of Lahore, which lies near Cashmere. It is used for torches or lamps by the natives, cut into small slips; but neither turpentine nor tar are made from it. The northern sides of the hills which lie on the north of the province of Delhi produce the common Scotch fir in great abundance. Indeed, it is a tree by no means uncommon in the northern districts of Hindostan Proper. The timber of the pines that grow in the Terriani district, is remarkable for its straightness and durability; and from a species of the pine, called the Suli pine, Kota, a pure turpentine is procured. The willow is generally found in those parts of India where the pine thrives.

In the vicinity of Sautjur, among the Eastern Ghauts, the great American aloe, Agave Americana, grows in Aloe great profusion. The district of India most destitute of trees, is the barren sandy track of the Carnatic. Here the only trees that grow spontaneously are the Melia azadirachta, or brea, and the R fautia nitida. All the three species of Molca grows in India. The R. nit- ter is also found among the rich muddy soil on the banks of the Ganges.

Of the fruit-bearing trees, we have hitherto noticed only such as are also valuable and useful in other respects; but we must not omit the enumeration of a few of the most celebrated for their fruit alone. Of all the Indian fruits, the mango is generally deemed the most delicious. It grows both in a wild and cultivated state in almost every part of Hindostan, especially in the southern districts. Mazagory, near Bombay, is celebrated for this fruit. Mrs. Graham informs us "that the parent tree from which all those of this species have been grafted, is honoured during the fruit season by a guard of sepoy; and in the reign of Shah Jehan, couriers were stationed between Delhi and the Mahatta coast, to secure an abundant and fresh supply of mangos for the royal table. At Battalah, in the Punjab, a plum grows of excellent flavour, called by the natives aloocha. At Jambe, in Lahore, the white mulberry produces fruit of a large size, and remarkably fine flavour. The trees of this kind which are cultivated for the support of silk worms will be afterwards noticed. In the Silhat districts of Bengal, orange plantations occupy a considerable tract of land. They form the principal export of the country, and are sold on the spot at 1000 for a rupee. Grapes have been long grown in Aurungabad, near Poona, and in the province of Malvah; and, latterly, they have been introduced into Bombay. In the neighbourhood of Chikery, in the territories of the Paihwhah, grapes of an extraordinary size are produced. Near Oogain, in the province of Malvah, where the soil is very rich, the vine produces a second crop of grapes in the rainy season, but they are by no means of good quality, being very tart. In Bombay, in order to prevent the fruit from
setting at the commencement of this season, artificial means are employed to impede the growth. The Jum-
boo, a species of rose-apple, is esteemed not only for its fruit, but also for its crimson flowers, which hang down with much elegance from every part of the stem. Bes-
ides the grape, mulberry, fig, and a few other fruits, there are not many European fruits that grow in Hind-
dostan. There are some apple-trees; the largest and best grow in the province of Lahore, near Battalas. Two species of the papain fig, "remarkable for the sweet-
ness and rose-flavour of their fruit; the *apandius duleis, whose sweetness, pleasantly tempered with acid, renders it peculiarly agreeable in this hot climate; the *pillow, from the trunk and larger branches of which are produced fibrous barks, sometimes of the weight of 25 pounds, which are filled with nuts like the chestnut, and resembling the almond in flavour; the *dillenia In-
dica, remarkable for its beauty, and valuable for its large pomaceous fruit of a pure acid, and equal to the white lily in fragrance; the *averhoa carambola, which produces three crops of fruit in the year; and another of the same genus, which is in a manner covered with large juicy berries of the size of a hen's egg, and re-
semble the grape; and the elephant apple, almost equally a favourite with the animal whose name it bears, and with the native Hindoo," are mentioned by Mr. Aikin as some of the most celebrated fruit-bearing trees of India.

After premising that the red lotus, the most beauti-
ful of the nymphaeas, is common on the banks in the south of India, and that the sensitive plant grows sponta-
neously in the Amarn district of Guzerat, we shall con-
clude our account of Indian botany, (with the excep-
tion of a short notice or two regarding some of the grapes,) with another extract from the author whom we have just quoted, in which he is describing some of the trees, shrubs, and herbaceous plants that are re-
markable for their size or beauty. "The *kipicus je-
valaeus is remarkable by its magnitude and the pro-
fusion of its elegant blossoms; and is of peculiar value in a tropical climate, as hardly any insects are found
under its shade. The cotton tree rises with a thorny trunk eighteen feet in circumference, to the height of 50 feet without a branch; it then throws off numerous boughs, which are adorned in the rainy season with purple blossoms as large as the open hand, and these are succeeded by capsula filled with a fine kind of cotton. The shrubs and herbaceous plants are innum-
erable, and multitudes would be well worth record-
ing for their beauty or use, if the nature of this work allowed an opportunity; we cannot, however, omit the indigo and Indian madder, whence the beauti-
tiful colours of the Indian chintzes are procured. The *ayatanus hirsuta, and the *jasminum grandiflorum, boast the most flagrant blossoms of the whole East, the former perfuming the night, the latter scenting the day. The *glorisoo superba, and Indian vine, form, by their union, bowers worthy of Paradise; and the *butea superba, a small tree, by the striking contrast of its green leaves, its black flowery stalks, and its large scar-
let papilionaceous blossoms, attracts, with its ostenta-
tious charms, the notice and admiration of the most in-
curious."  

Kossa grass.  

Of the *pos, the *pos cynosourides, the kossa grass of the natives, deserves particular notice. It is regar-
ded as a sacred grass, and is held almost constant in the hands of such as are anxious to be regarded as par-
ticularly devout; it is used at sacrifices. It is also of considerable use in this climate, since from the roots of it a kind of mat called *tatt is made, which are placed against the doors or windows, and constantly watered, in order to keep the rooms cool; as its fragrance is plea-
sant, it thus spreads an agreeable scent as well as fresh-
ness through the apartments. On the eastern frontiers of Bengal, there is an immense extent of land covered by a peculiar kind of grass, called by the natives the augeah grass. The soil on which it grows is sandy; it *Augeah grass.
grows to the height of 30 feet, and is as thick as a man's wrist. The jungle grass is very common in many parts of Hindostan. In the Ragamal district of Bengal, it gras.

But we must conclude this desultory account of In-
dian botany, merely remarking, that when we come to treat of the agriculture of India, we shall have occasion to notice some plants, which more properly fall under that head.

The native breed of horses in India is a small ill-
shaped vicious pony, in some parts not exceeding 30 inches in height, particularly on the confines of the Nepaulese territories. Wild horses, of a hardy and useful breed, spotted in a singular manner, and with great variety of colour, are regularly brought from the banks of the Bontsu, in Nepal, for sale, into Hindo-
tan; they are called tanyans. There are also a great many horses brought from Candelah and Tibet, and sold at the annual fairs of Hindostan. In some parts of the country itself, however, the breed of horses is good; and as most of the Hindoo princes, as well as the British, are obliged to have numerous cavalry, con-
siderable attention, as may be supposed, has been paid to the improvement of this useful animal. In the Cho-
teenur district of the province of Gundwana, brood
mares of the tattoo species are kept in considerable numbers. This is the same species that is common in Bengal; it is a thin ill-shaped animal. The horse
commonly used by the Mahrrattas in war, is also a poor looking animal, about 14 or 14½ hands high, with large bones; but in the Poo, the Mahrrattas, particularly near the Beemah river, there are excellent and beautiful horses, of a middle size, generally of a dark bay col-
our, with black legs, which are highly esteemed by the Mahrrattas; they are called Beemarteddy horses, from the district where they are bred. In the province of Aurungabad, also, great numbers are reared for the Mahrratta cavalry. These, however, are neither strong nor handsome, though they are of a hardy breed. The Mahrratta cavalry almost entirely consist of mares. In that part of the province of Bahar which lies near the Nepaulese territories, a great number of horses are bred for the British cavalry. It has been satisfactorily ascertained, that this animal degenerates in size, and in most of its useful qualities, in low and moist situations; hence it is supposed, that the horses of Bengal are of such an inferior description and small size, some of them being no larger than mastsills. In dry and moderately elevated situations, on the contrary, they not only thrive well, and attain a good size, and are strong, active, but handsome. Since the British began to pay attention to the breeding of them in the northern parts of the province of Bahar, many of the very first quality have been reared there, particularly in the districts of Tyrprot and Hajiyeer; and they are in such request, that horse dealers from Upper Hindostan in particular, go to the fairs at Huriwar and other places to purchase them.

Farther to the north, however, where the country be-
comes very mountainous, the horses fall off in point of
size; but though nearly as small as those of Bengal, they are much more handsome, active, and strong. The British have also frequently obtained horses from the middle districts of Guzerat and from Lahore; the latter are particularly excellent. Those from Guzerat consist principally of two breeds, from Cottiwarr and Werrcar; the latter are small in size. They are exported to the territories of the Rajah of Joulpoor.

In some parts of India, the ass is a common and useful animal, particularly in Bengal, the Carnatic, and above the Ghaouts. They are small-in size, and are distinguished by the great variety of their colour. There are some entirely black; and it is remarkable of these, that there is no appearance of the cross on their shoulder. This animal seems regarded with various feelings in different parts of India. It is generally deemed an animal which none but the lower castes would ride on, or otherwise employ; and yet in Mysore, if a dispute arises in a village, one of the parties frequently terminates it by killing a jack-ass. By this, indeed, they both suffer; for no Hindoo would remain in the place where the ass was killed, and consequently they are both obliged to fly. This singular mode of revenge, if so it can be called, is also had recourse to by the inhabitants of Mysore, when they consider themselves aggrieved, oppressed, or affronted in any thing relating to their caste by their rulers. The milk of the ass is never used. Herds of wild asses are sometimes seen near the mountains in the north of Hindostan.

The cattle kept in India are the common black cattle, and the buffalo. They are both very numerous, particularly in the coiled districts, where, in the year 1806, there were 1,198,615 black cattle; and 1,147,492 buffaloes—in Bengal, where it is supposed that there are of both kinds above 50 millions—in Guzerat, where the bullocks are reckoned the strongest, swiftest, and handsomest in India, from the Choteesgur district of this province, which contains about 20,000 square miles, part of which, however, is mountainous, or covered with jungle, they export in favourable seasons 100,000 bullocks. The British government in India have paid considerable attention to the improvement of the breed of bullocks for their ordnance; but there are only two districts in the Bengal presidency, in which bullocks of a size required by the British for this purpose are bred—the Purneas district of Bengal, and the Sarun district of Bahar. The bullocks of the former are of a large size, very strong and active, well formed, and much superior to the cattle employed for draught in the lower parts of Bengal. The bullocks in the Sarun district are not so excellent in their qualities; nor so large; but they are little inferior in these respects. Upwards of 5000 from these districts are employed by the Bengal government for the conveyance of artillery, camp equipage, &c. besides elephants and camels. The natives in these and the adjoining districts have 'made no attempts to improve their breed of bullocks, notwithstanding the example and success of the British. The common draught cattle all over India have a hunch on their shoulders, on which the yoke rests; they are of a white colour, small size; but active and well proportioned—as used in agriculture, they will be afterwards considered, as well as the buffalo. See Buffalo.

The sheep in India are small, generally of a black or dark grey colour, with wool-like hair for hardness and coarseness, and scarcely fit for any purpose. In Allahabad and on the Coromandel coast the sheep are small, and of an inferior quality, even compared with those of Bengal. In the year 1806, the number of sheep in the ceded districts amounted to 1,147,492. They are also numerous in the Mysore, where they are of three varieties of colour, red, black, and white. Here the shepherds and their families live with their flocks; the men sleeping in the open air among their sheep, wrapped up in blankets; and the women and children under baskets made of leaves, and about six feet in diameter. These baskets will keep out the rain. On one side of them is a small hole, by which they creep into them. As there is no door or covering to it, it is always turned from the wind or rain. Of the sheep in the south of India, there are the most sheep bred in that of Coimbeetoor, particularly in the Arumass district of it. There are in Bengal a few sheep with four horns, superior in size, and better proportioned than the common kind. Goats are by no means uncommon in the hilly districts of India. They resemble in size, &c. the European goat. In the year 1806 there were 694,639 in the ceded districts. Swine were common in the Mysore till they were almost extirpated by Hyder Ali. They are not numerous in any part of Hindostan, either domestic or wild.

Next to the animals which we have described, in Elephant, Cattle, and Buffaloes. the ass is a point of use, and indeed before some of them in this respect; the elephant claims our attention. In the elephants of India there is a considerable variety, with respect not only to size, but also to colour, and the length of the tusks. They seem to be generally a blackish brown colour. Sometimes an elephant of a reddish colour is seen in the forests; but this is supposed to arise from the red earth in which it has rolled itself. White elephants are rendered so by disease. The best elephants are reckoned to be those of Chittagong, and generally such as are found near the sea. In the Tipperah district of Bengal they are very numerous, but not of the first size or quality. On the mountains in the north of Hindostan, they are still smaller, seldom exceeding seven feet in height; these are frequently caught merely for their teeth. With respect to the height of this animal, it appears that of 150 elephants employed in the service against Tipperah, there was only one which reached the height of ten feet. The height required by the British government in Bengal for the elephants which they purchase for the service of the army is nine feet. The common height of the Indian female elephant seems to be from seven to eight feet; and that of the males from eight to ten feet, measured at the shoulder. The largest ever seen in Hindostan measured 10 feet 6 inches at the shoulder. It was caught in the year 1796, and belonged to the Nabob of Oude. The largest tusk in Bengal very seldom exceed the weight of 70 or 80 pounds. See Elephant.

Camels are bred in that part of the Delta of the Indus. Camels, Carcey, which is nearest the sea. On the sea beach and sandy slips in that part of Guzerat which is separated by the main land by the Run, they are suffered to run wild among the jungles, the tender parts of the brushwood serving them for food; they are, however, of an inferior description. The camel is not unfrequent about Patna; they are employed by the British government in carrying military stores, &c. See Camel.

Notwithstanding the positive opinion of Mr. Pennant, that the lion is met with near the fort of Gwalior, in the province of Agra, it is generally believed by naturalists and travellers, that this animal is not a native of Hindostan. "The royal tiger of Bengal, however, is a far more terrible animal than the stoutest lion, and was known in classical times, as Seneca the poet calls it Gangetica igeris, or the Gangetic tiger. Such is their size and strength, that they are said to carry off bul-
locks; the height of some being said to be five feet, and the length in proportion. Parties of pleasure on the isles at the mouth of the Ganges have often been shockingly interrupted by the sudden appearance of the tiger, prepared for his fatal Spring, which is said to extend to a hundred feet.—Not improbable, when compared with that of the cat. Such is the nature of the animal, that if disappointed in his first leap, he couches his tail and retires.

In the northern district of Coimbatore, there are a great number of black bears, which, however, are very inoffensive, living chiefly on the white ants, and the fruit of the palmrya. Near Chittagong there is a species of bear which is called there the wild dog. "His head is shaped like that of a dog, but bare and red about the muzzle; his paws are like those of the common bear, but his coat is short and smooth."—Graham's Journal, p. 143. This animal is very ferocious, and will not eat any kind of vegetable food. The one-horned rhinoceros is not uncommon in the islands of the Ganges. Antelopes, especially that species called the Nylgrau, are numerous, and of a large size; the hunting of them by the leopard, is a favourite sport among the Indian princes.

Tippoo was very fond of it. Apes and monkeys are common; and it is said, but not on very good authority, that the orang-outang exists in the forests to the west of the northern Circars. The other quadrupeds are dogs, of the cur kind, with sharp, erect ears, and pointed noses; bears, wolves, foxes, jackals, hyenas, panthers, lynxes, &c. The moschus, moschiferus, or musk-deer, is an inhabitant of the mountains which lie on the north of Hindostan; but the musk that is brought from Bengal is of a inferior kind to that which comes from China.

The birds of India are very various, and some of them uncommonly beautiful. This is the native country of the peacock, where they exist in abundance, in almost every part, in a wild state, and are much larger, and produce a greater number of eggs; proofs that in India they are in their natural climate. They lay 20 or 30 eggs in the course of the year. Near Casmay, and in different parts of the province of Malabar, they are particularly abundant. At the first mentioned place they are caught in a very simple and singular manner. A piece of canvas, on which are painted the figures of peacocks, and to which are attached two lighted candles; is fastened, during the night, to the tree on which they are perched; and the birds, being either deceived by the figures, or dazzled by the light, stretch out their necks towards the canvas, and are caught in a noose which the concealed bird-catcher holds. The historians of Alexander mention the delight and surprise with which that conqueror first beheld the peacock, and that he forbade them to be killed under very severe penalties.

There are few birds, natives of India, so remarkable, and which has excited so strongly the attention of naturalists, as the goose-beak, (Loria philippiana,) the olomari of the Malabars. It is described in the Asiatic Researches, by Har Ali Khan of Delhi, as "rather larger than a sparrow, with yellow brown plumage, a yellowish bill and feet, and light coloured breast, and a conical beak, very thick in proportion to its body." They chiefly frequent the coura-nut trees, or the palmmyra and Indian fig, being evidently partial to a lofty site for its nest. This bird constructs its nest in a very curious way, with the long fibres of plants or dry grass, and suspends it by means of a kind of cord nearly half an ell in length, from the extremity of an extremely slender branch of the tree, in order that it may be inaccessible to snakes and other animals, which might destroy its eggs or its young. This hanging nest, though agitated by the wind, is so strongly secured, that it never suffers the least injury. The interior part of it consists of three neat apartments or divisions. The first, which forms the floor part, is occupied by the male; the second is destined for the female; and the third contains the young. In the first apartment, where the male always keeps watch, while the female is hatchling the eggs, a little tough clay is always found stuck against one side of it; and in the top of this clay is a glow-worm. Bartholomaeo, from whom this account is taken, thinks that the glow-worm serves to afford light in the night time; but it seems much more probable that the bird feeds on these insects. This bird is much valued in Hindostan for its docility, and attachment to those who domesticate it. The common fowl is found in the jungles, and is called the jungle bird; and the wild cock, the feathers of which are of various colours, and shine like gold, is found in the Ghauta and the adjacent forests. The Pelicanus onocrotalus, or large Asian pelican, is found in Malabar. This province is also the native country of what are called the Malabar bat, Vesperilisa vampyrus, or caninus, and which seem to differ from the vampire bat of Surinam. The Granella religiosa, which are common in the districts adjoining the Ghauts, is a bird held in considerable esteem by the natives on account of its song; its body is quite black, and its head is covered with a hood of a bright yellow colour. This bird is called Mina by the natives, and is often seen with the kokola and other birds of song, together with a bird as small as the humming bird, which fixes its nest to the pointed tips of the palmrya, to secure its young from the tree snake, in the gardens, under the shade of the trees, in the vicinity of Bombay and other towns. The Eirurus, the largest of aquatic birds, is found among the lakes in the north of Hindostan Proper, where it is kept by the natives in their gardens, for the purpose of picking up the vermin. Parrots of almost all the varieties with respect to size and colour, abound in Hindostan.

Snakes abound; the cobra naia, cobra de capello, snakes, &c. the most poisonous of all the species, is one of the most common in Malabar, where there is also a snake resembling, in the rings round its body, the cobra naia of Europe, but much smaller, and very poisonous. The mountain snake of the Ghauts seems to resemble the boa constrictor, as it is represented by Bartolomeo, as being from 30 to 40 feet long, and as thick as a full ox, and as devouring hogs, deer, cows, and other animals, which it seizes by twisting itself round their bodies. Mrs. Graham mentions the same kind of snake as common in the vicinity of Bombay, where the cobra de capello, and the cobra manilla, and a small bright speckled snake, and, in short, snakes of all sizes, are constantly gliding about.

The insects are also very numerous, and in great variety in all parts of India. The termites fatale, or white ant, which is particularly noticed by Herodotus and Arrian, is very destructive to furniture, clothes, &c.; they are eagerly devoured by the Chansu Carir, a wretched and deserted caste in the Carnatic. The meloe ecorci, or triamulma, is found in great quantities in the Deo in, and in that track which stretches along the right bank of the river Jumna; it seems to feed on the solanum melongena, and makes its appearance at the commencement of the rainy season. The meloe ecorci is principally found in Bengal, Berar, and Oude; it subsists on the flowers of the cucurbitaceous plants, and also on those of the hibiscus and sida species; it is most abundant during the rainy seasons. Both these species
of meloe may be used as medicine instead of the Spanish blistering fly. The fire-fly is very common in India, and is one of the most beautiful insects of that country; the trees are sometimes so completely covered with it, as to appear like "pyramids of light." The most troublesome insects are the flies, mosquitoes, and chincunes, or bugs; and the small worm which deposits its eggs under the skin; this last is particularly troublesome.

In our account of the fish of India, we must be equally concise as we have been in describing some of its quadrupeds, birds, snakes, and insects. In the Ganges there is great variety and abundance of fish; but of all the kinds found either in this river, or in any other part of India, the most delicate and high flavoured is the mango fish; it receives the name because it appears in the rivers while the mangoes are fit for use. The Europeans in India esteem them most highly, especially during the time when they are full of roe. The other kinds of fish in highest repute for their flavour, by Europeans, are the cockup and the sable fish.

The coast of Chittagong is celebrated for oysters, particularly near the island of Cutubdia; they are here small, but of an excellent flavour, and are sent by the inhabitants to Dacca and Calcutta. Oysters are also exceedingly plenty in the rivers of Cochin, where they are fished for in the same manner as the pearl-oyster.

Turtle are found in the Ganges, but small and of inferior quality. The salmon frequents the sea coast, and the rivers of Malabar; and pilchards in immense abundance are found on this coast. In the Alacananda river there are a great many fish of the cyprinus genus, particularly C. denticulatus, which grow to the length of four or five feet; there are some, it is said, even seven or eight feet long; these are represented as very beautiful; the scales on the back and sides, which are very large, and of a fine green colour, with a bright gold edge; the belly is white, with a slight tinge of gold colour; the tail and fins are of a dark bronze colour. This fish is very delicate and rich in its flavour; and many of them are so remarkably tame, that they take bread, &c. out of the hands of the Brahmins, by whom they are daily fed. Alligators and porpoises are common in the Ganges. The whale, which the natives call the sea elephant, is sometimes seen off Cape Comorin. The sword fish is very abundant in almost all parts of the Indian seas. Crabs are represented as poisonous, or rather very unwholesome in the months of October and November, in consequence, it is supposed, of their feeding on poisonous aquatic plants. The sea hedge-hog; sea-star; pipe corillio; sea-nettle, &c. are common in the Indian seas.

Mineralogy.

The mineralogy of India has not been very carefully or thoroughly explained; there are, however, some parts of it which are well ascertained, and are very important and interesting. To begin with the Ghauts; these mountains are composed of a granite, in which the feldspar and quartz, both of which are remarkably white, bears more than the usual proportion to the mica, which is of a dark green colour. The particles are angular, and of a very moderate size. These are evidently strata, but in general they are so very much confused and broken, that the line cannot be well defined. In the Coimbetoor province, however, the strata of the Ghauts evidently run north and south, and are vertical; they are much intersected and broken by fissures, which renders the stone not of much use in building. Many of the masses of rocks in the Mysore country, on which the almost impregnable fortresses of Tippoo were built, are of granitic porphyry, and rise into high sharp peaks. Granite seems to form the principal mountains in Hindostan, as well as the Ghauts; it is found mixed with the soil in the neighbourhood of R unjust, a town situated on the south-west side of the Ganges, latitude 25° 2', but not lower down the river. Limestone is found in many places, particularly among the hills near the bed of the river Palar, in the vicinity of Aroet, where it is found in the form of nodules. This species of limestone is the chunam, that is used by the natives along with the areca-nut and betel. Chunam is also met with in almost inexhaustible quantities in the Sihit district of Bengal; and from this district Calcutta, and the most remote parts of the province, are supplied with it. In the neighbourhood of Bombay a good deal of chunam is made from shells, and the natives are very particular in gathering them, and in burning each sort separately, as it is said that the chunam varies in its qualities and value, according to the kind of shell from which it is made. The Madras chunam is smooth, hard, and polished as marble. Most of the public offices in this town are built of it. There are marble quarries of considerable extent, which yield marble of excellent quality, in the province of Ajmeer, near the town of Pookshur, which is much employed in building. Other stone proper for building, particularly what is called the Theban stone, is very abundant over Hindostan Proper, and is by no means rare in the Decan and the south of India. In Bombay there are large quarries. In one of the branches of the Ganges, as well as in other rivers, a very rare stone is found, which is regarded with much veneration by the followers of Vishnou. It is described as very heavy, commonly of a black colour, and sometimes violet; round or oval in its form; a little flat, and nearly resembling a touch stone. It is hollow in the inside. There is only a small hole on the outside, but within it is almost concave, and furnished in the interior coats, above and below, with spiral lines, which terminate in a joint towards the middle, and in many these two points touch: (Sonnerat, i. 41.) In the province of Oude, lapis lazuli, of an excellent quality, which sells in England for nine guineas an ounce, is found.

The diamond mines of India have been long known and celebrated. The most remarkable is that of Panjah, which seems to have been known to Ptolemy. The Emperor Achar, among his other plans of improving and enriching his territories, paid great attention to this mine, from which he drew eight lacks of rupees annually. The native chiefs of Bundelcund, (in which district of Allahabad, beyond the range of mountains extending from Rhotas to Ajmeer, Panjah is situated), as well as the last Mahratta conquerors of this district, also drew considerable revenue from this mine. Subsequently, however, it seems to have declined; for in the year 1756, they yielded to the Rajah only four lacks of rupees. Of their present state, nothing accurate is known. Besides the diamond mine of Panjah, there is one other to the north of the Decan, near Sumbhulpool, in the province of Gundwana, near the junction of the Hebe with the Mahahndy. In the year 1768, a journey was undertaken to this mine, under the direction of Lord Clive, by Mr. Motte; but he was not permitted by the Rajah to reach it. From the information which he collected, however, in Sumbhulpool, we learn, that the "natives search in
the river Hebe after rains for red earth, washed down from the mountains, in which earth the diamonds are found." This matrix was examined by Mr. Motte; it was a clay nearly as red as burnt bricks. Till the period that this district was overrun by the Mahtrattas, the natives informed Mr. Motte that they used to go to the mountains and dig for diamonds; but this practice they have discontinued, as it would only increase the tribute which they were obliged to pay to their conquerors. The other diamond mines in Hindostan are to the south of the Nerbuddah. About the middle of the 17th century, the diamond mines in Sedbouth, a district in the Balaghat district, were productive, but these, as well as all the other diamond mines of Hindostan, have long ceased to be very valuable, being either exhausted or neglected. There are also mines at Raoleonchah, about 40 miles N.W. from the junction of the Beemah and the Krishna; at Coleore, on the southern bank of the latter river, not far from Condavir, in the Gentoor circuit; and in Colonda, Cornelian and other opake stones are found near Camelb-, and garnets near Hyderabul.

Gold.
The metals found in Hindostan are gold, iron, and lead; there are not any indications of silver; and with respect to copper, though it is enumerated by some authors among the metals of Hindostan, there seems no foundation for the statement. * There are no mines of gold; this metal being only found among the sand washed down by the rivers. The quantity thus obtained from the Indus and its tributary streams, was probably much more in ancient times than it is at present, as Herodotus informs us, that the tribute paid by the Indian Satrapie of Persia to Darius Hystaspes was in gold, and that the sum paid was nearly one-third of the whole tribute paid by all the 20 Satrapies. In the Ayin Abarree, we learn, that gold was found in the channels of the Ravey and Kemonoon. The nearer these and other rivers in the north of Hindostan are to their source, the more gold dust is found in their channels. In many of the rivers of Assam, that flow into the Brahmapoota, it is by no means uncommon, especially in the Dekrung, which is famous, not only for the quantity but the quality of its gold. In the eastern extremity of the Rajah of Mysore's territories, nine miles to the east of Boodicotta, an area of country comprising 180 square miles, is said to contain gold dust. In the Fernadu district of the province of Malabar, gold dust is found in a branch of the river which falls into the sea at Paravpana.

Iron ore is not common; it seems to be chiefly bog iron ore, or particles of iron mixed with sand. Of the latter, there is a considerable quantity in the Mysore Rajah's dominions, not far from Severndroog, the sand is nearly black with it. It is collected during the rainy season in quantities sufficient to keep a furnace employed the remainder of the year. There is also abundance of iron ore in the same part of the Mysore at Ghettupar, but of what kind we are not informed. Steel is manufactured here. Black sand, mixed with iron ore, is brought down in the rainy season by the torrents from the Eastern Ghaut, near Naikshan Fery. The smelting is carried on during the dry season, each forge using a certain quantity of iron for permission to carry on the work. Indeed, the Mysore seems to be more abundant in this metal than most other parts of Hindostan. At some of the iron works, 47 per cent. of malleable iron is obtained from the ore, but it is by no means in a pure state. On the western side of the south of India, the metal in the Velater district of the province of Malabar, where there are many forges, but here also, and indeed all over India, the work is performed in a very ignorant and careless manner, pieces of charcoal being frequently enveloped in the iron after it is smelted. In the Singrowla district of Gundwannah, this metal abounds; the price being from one and a half to two and a half rupees per 80 lb. according to the quality. The highland district of Bahar is also rich in iron, which is fused for sale by the natives in large quantities. In the south-west coast of the Guzerat peninsula, there are likewise extensive works for fusing this metal. There are lead mines in the territories of the Rajah of Joudepur, in the province of Ajmeer.

The manufacture of salt from the sea water, and of rock-salt, will be noticed afterwards; but this is the proper place to notice the mines of rock-salt in Hindostan. These lie in the district between the Indus and the Hy- other..

India.

In treating of the climate of India, the monsoons first claim our attention. It is generally said that the monsoons do not extend beyond the tropics; this, however, is not accurately the fact, as will be afterwards noticed. At present, however, we shall regard them as merely blowing on the coast of India, from Cape Comorin to the tropic, and point out their effects on the climate of this region.

On the Malabar coast, the south-west monsoon commences about the middle of April, and continues till the months of August or September; it begins to blow first on the southern parts of this coast, and gradually advances to the north. In September it has generally lost its violence; and for the next six weeks there are light variable winds. At the latter end of October the north-east monsoon begins on this coast; this also blows first in the south, and about 15 days afterwards is felt on the northern parts of the coast: this monsoon continues till April. On the Coromandel coast the south-west monsoon begins about the end of March or early in April; but it is not regular or strong till the month of June, and the monsoon breezes being not uncommon in March, April, and May. In June, July, and August, this monsoon is very steady, regular, and strong; but even during these months, a land or west wind blows from the shores for 24 or 48 hours. In August and September the south-west monsoon begins to lose its steadiness and violence; and the north-east monsoon commences about the middle of October; from this period till the beginning of December, it is very boisterous, and navigation is rendered extremely dangerous; but in December, January, and February, it is steadily well settled weather. On both coasts, the setting in of the monsoon is generally attended by violent hurricanes.

Such is a short description of the monsoons as they appear on the western and eastern coasts of India; but before we proceed to point out their effects on the climate, it will be proper to advert to the circumstance of their extending beyond the tropics. This is decidedly the case at Tatta, which lies in 24° 44'. The monsoon, however, does not reach Corachin in latitude 24° 31'. There are indeed at this place, as well as along the coast of Mekran, from April to October, south-west and west winds; but, as they often vary and change, in the north and north-west, they cannot be regarded as monsoons, especially as they are seldom attended with squalls and rain,—the invariable marks of the south-west monsoon on the coast of Malabar.

The climate of that part of India (as far as respects rainfall) in which the monsoons prevail, and the Ghauts are situated, is uncommonly regular. It will easily be conceived, that when the south-west monsoon prevails on the coast of Malabar, this coast will be deluged with rain, in consequence of the Western Ghauts intercepting the clouds brought by this monsoon; and that the same monsoon, on the Coromandel coast, will occasion dry weather: while, on the latter coast, the rainy season will be occasioned by the north-east monsoon, which dashes the clouds, surcharged with moisture, against the Eastern Ghauts. On the Malabar coast, on the contrary, this monsoon will occasion dry weather. Hence it appears, that the rainy season on the Coromandel coast must commence with the north-east monsoon, about the middle of October, while at that time the dry weather begins on the coast of Malabar; and that the rainy season on the Malabar coast must begin in April or May, the period of the commencement of the dry season on the Coromandel coast. The rains on this coast are not, however, so violent as those on the Malabar coast. This seems to arise from the circumstance that the Eastern Ghauts are farther from the sea than the Western; and, consequently, the clouds are not so soon broken, and have also a greater space over which they can spread themselves before they are broken. It is not improbable, too, that the greater height of the Western Ghauts may intercept a larger portion of the clouds than the Eastern, and break those which it does intercept more completely. As the Western Ghauts extend no farther than the latitude of Surat, the south-west monsoon, to the north of this latitude, as far as it blows, carries the rain without interruption over the whole country. We have already mentioned the break in these Ghauts near Panjany. In consequence of this break affording a passage to the north-east monsoon from the Coromandel coast, ships which navigate the Malabar coast commonly experience a stronger gale in the neighbourhood of Panjany than they will suffer part of this coast. The lower part of the province of Coimbeeteur partakes of the rainy monsoon of the Malabar coast, which is probably occasioned by the same break permitting the south-west winds to blow through the Ghauts in this part.

The south-west monsoon blowing so long, and part of the time with such violence, forces a great body into the Gulf of Bengal; and, during its prevalence, the surf on the Coromandel coast is very tremendous. The north-east winds continue this surf, by impelling the waves on the shore, which is very steep, having, as was before observed, no soundings at the distance of thirty miles. As soon, however, as the north-east monsoon begins to abate, that is in December and January, and the south-west current, which prevails in the Bay of Bengal, can operate, the surf on the Coromandel coast is by no means high or dangerous.

Having thus briefly explained the monsoons and their effects in the southern part of India, we shall now make some observations on the climate, as it respects wind, rain, and heat, in other parts of this country. In that part of Bengal which lies near the head of the bay, the wind blows alternately from the north and south, dur-
The northerly wind prevails during the cold season, that is, during October, November, and December; and the southerly one during the hot, that is, from March to the end of May. In the eastern parts of Bengal, a north-west wind begins about the middle of March. During the prevalence of this wind, there are sudden and violent squalls of wind and rain, which are often very destructive to the boats on the Ganges. These squalls are more frequent in the eastern than in the western parts of Bengal.

Daring the season, rain falls in Bengal generally divided into cold, hot, and dry; but the natives are more minute in their divisions, assigning six seasons to the year. The spring and dry season occupy four months, that is, February, March, April, and May. The periodical rains commence nearly at the same time over the whole of this part of Hindostan, that is, in the beginning of June. During the first two months there is scarcely an interval of two dry days; and the rain falls in such abundance, that four and five inches have fallen in the course of a single day. In August and September the intervals are more frequent and of longer duration, and the weather becomes sultry. As the cold season approaches, fogs and dews are very common and dense. This description of the climate of the province of Bengal will apply, in almost every particular, to the climate of the whole of Hindostan Proper, except that in the mountainous parts the rainy season begins early in April. In Balhar also, and the contiguous districts, a strong parching wind blows from the west during the greatest part of the hot season; but it is not steady, nor very regular; for it sometimes ceases altogether, and is succeeded for a few days by an easterly wind; and even after a parching wind from the west in the day time, a cool easterly breeze will set in at night. To the west of this province these parching winds are more frequent, as well as more oppressive and prejudicial to vegetation.

When the quantity of rain that not unfrequently falls in Bengal, in the course of a single day, during the rainy season, and the long continuance of that season, are considered, we shall not be surprised, that the average annual fall of rain in the lower parts of the province should be between 70 and 80 inches. During the south-west monsoon at Bombay, the quantity of rain generally exceeds 100 inches; sometimes it reaches 110 or 112 inches. At Madras, according to Mr. Cockburn, who was examined before the Select Committee on the affairs of the East India Company in the year 1818, upwards of 50 inches fall in the course of one month; and yet he estimates that only from 45 to 70 on or 50 inch falls in the course of the year, according to the situation and severity of the monsoon. During the first part of the rainy monsoon on the coast of Malabar, that is, in the months of May and June, a considerable quantity of rain falls in the Table-land of Mysore; but it is uncertain whether this is the effect of the monsoon, or is merely the periodical tropical rain. In the north-western extremity of the Rajah of Mysore's territories, on the summit of the western Ghauts, there are usually nine rainy months in the year. During six of these months the rain is so violent and constant, that it is impossible to go abroad, and "it is customary to make the same preparatory arrangements for provision, (water excepted,) as are adopted in a ship proceeding on a voyage." The elevation of this part of India is so great, that the climate is a month later than it is on the sea coast. In the mountainous parts of the province of Coimbatore, there are two rainy seasons; the first is in April, and the second in July, August, September, and October. The north-west parts of Hindostan Proper seem the driest with respect to climate. During the greater part of the south-west monsoon, or at least in the months of July, August, and part of September, (which is the rainy season in most other parts of India,) the atmosphere is here generally clouded; but no rain falls, except very near the sea. Indeed very few showers fall during the whole year. Captain Hamilton says, that no rain had fallen during the three years preceding his visit to Tatta. Owing to this, and the neighbourhood of the sandy deserts which bound it to the east, and are not far removed from it in the north-west, the heats are so violent, and the winds from those quarters so pernicious, that the houses are contrived so as to be occasionally ventilated, by means of apertures on the tops of them, resembling the funnels of small chimneys. When the hot winds prevail the windows are closely shut, by which the hottest part of the current of air (that nearest the surface, of course) is excluded, and a cooler part, because more elevated, descends into the house through the funnels. By this means also vast clouds of dust are excluded, the entry of which alone would be sufficient to render the houses uninhabitable."

The general temperature of India, it is evident, must be very high, especially in those parts, which, like Sind, are of a sandy soil, and dry climate, and in the more southern provinces. In the more elevated regions, however, a considerable degree of cold is often experienced. At Calcutta, the following is the range of the thermometer from October to April, with the prevalent winds during that period.

In Calcutta, the heat is sometimes so intense that pigeons drop down dead at noon, while flying over the market-place. In the middle districts of the province of Bengal there are occasional thunder storms during the hot season, which render the atmosphere cool; and in the eastern districts the same effect is produced by occasional showers of rain. In the higher parts of Bengal, the weather is sometimes very cold. Between the latitudes of 28° and 29°, in the province of Delhi, the heat during summer is very intense; but when the wind blows from the northern mountains in the winter, the thermometer falls below 30, and water freezes in the tents. The same description applies to the Shahrampore district of Delhi, which lies farther to the north, principally in the Doab. But the cold here is moderate, compared with what it is in some parts of Northern Hindostan. At the end of May in the year 1806, there were masses of snow, about 70 feet in thickness, lying undisturbed on the road to Bhadrinah, in latitude 30°. Even in the Benares district of Allahabad, the cold of the winter is so severe, as to render fires necessary, while in April, May, and June, the heat is very oppressive. The winters in the Decan, which contains a large portion of high land, are cold. At Hyderabad, and the
provinces to the north of it, the thermometer during three months often as low as 45°, and sometimes down to 35°.

The climate of Sind, on the north-west coast of India, has been generally described. It may be added, that in the months of June and July, the thermometer ranges from 90° to 100°. At Surat, the variations are in the course of the year from 59° to 96°. At Bombay from 63° to 93°; the former about the end of the year. The hottest months in the Malabar coast are April and May. In the former month, the maximum height of the thermometer at Cochin is 105°.

The temperature of the coast of Coromandel is in general much higher than that of the provinces on the coast of Malabar; and the Carnatic and the north-west extremity of the northern Circars are deemed the hottest, not only on the Coromandel coast, but in all India. In the latter district, the French, in the year 1757, lost seven European soldiers in the course of a single day by *coup de soleil*. The Circars, generally, have certain varieties in their climate, pointed out by Mr. Grant in his Political Survey of them, printed in the Fifth Report of the Committee of the House of Commons, on the affairs of the East India Company, which deserve to be noticed. To the north of the Godavery, a westerly wind, with moderate showers, begins about the middle of June; about the middle or end of August, the rain becomes more violent and regular; and it continues so till the beginning of November, when stormy weather takes place, and the wind shifts to the north-east. The weather continues moderate, with respect to temperature and rain, till the middle of March, when the hot season commences. To the south of the Godavery, the climate of the Circars is different in some respects. During January and February, the wind blows along the shore strong from the south; and as the sea breezes set in regularly every day, the temperature is moderate. In March, the hot season commences; and as the wind blows from the west over a loose, parched soil, and along the sandy and almost dry bed of the Krishna, the temperature is most oppressive; the thermometer being sometimes raised, near the mouth of that river, to 110° for several days, even in the house, and seldom falling under 103°. In the low country of the Arcot district of the Carnatic, during the hot season, the thermometer, under the corner of a tent, rises to 100°, and, when exposed to the sun, to 120°. If the annual heat at London be considered as represented by 100°, that of Madras will be 156°, and in July 1549; and if the cold in January in London be considered as represented by 1000, that at Madras, during the same month, will be 491. Taking the average of the whole year, the heat at Madras is less than that of Calcutta. In January the thermometer is about 70°; this is the lowest temperature: the highest is in July, when the thermometer is about 91°.

The soil of Hindostan exhibits fewer varieties than might be expected in such a vast tract of country. In the whole of that district which is watered by the Ganges, the most prevalent soil is a rich black mould, evidently of alluvial origin. No other soil appears between the Tipperah hills on the east, and the district of Burdwan on the west, nor below Dacca and Borleah to the north; nor is there any substance so coarse as gravel, either in the Delta, or nearer the sea, than 400 miles along the course of the Ganges at Oudanulla. At this place, a rocky point, evidently stretching from the base of the neighbouring hills, projects into the river. In other parts of Bengal and the adjacent provinces, there is a considerable extent of clayey soil; and that this was the original soil, where the black mould is now found, is proved by the appearance of the beds of the rivers, which are of clay. The substratum of the soil in this part of Hindostan is properly in many places calcareous; in others clay; and in a few instances rocky. The soil of the Punjab resembles that which chiefly prevails in Bengal, and is equally fertile. As we approach to the south-west into Sind and Guzerat, the soil becomes more sandy. In Malwa, it is a deep, black, rich mould. Of this kind of soil there is one variety, named by the natives *eyreg*, which is deemed very unhealthy. The whole of the plains of Chitteldroog, in the Mysore, which is 10 miles from north to south, and 4 from east to west, consists of this kind of black mould to a great depth. The provinces of Gundyawah and Orissa contain the largest proportion of poor unproductive soil perhaps in all Hindostan. To the south of these provinces, the soil near the coasts both of Malabar and Coromandel is sandy, and generally of a poor quality. It is more fertile, however, as the mountains are approached. In the province of Malabar, the soil at the foot of the low hills which intervene between the sea and the Ghauts, is a red clay, or brick earth. On the Coromandel side, the sandy soil continues nearly to the foot of the eastern Ghauts. The soil on the Table-land, and also in the extreme southern provinces of India, is of various quality; but, in general, a loam, on rock, very fertile.

**CHAP. IV.**

Different Tenures of Landed Property—Agriculture—

Wet and Dry Lands—Produce—Wheat, *&c.*—Rice—

Sugar—Ivory—Indigo—Poppy—Tobacco—

Mode of Harvesting—Implement—Pasture—Cattle—

Milk, Butter—Sheep—State of the Agricultural Classes.

It is foreign to the nature and object of this article, and would extend it far beyond its proper limits, to enter fully into the subject of the landed tenure in Hindostan, especially as, with respect to some points of it, there is considerable difference of opinion among the best informed authors. We allude particularly to the dispute which was for a long time carried on regarding the rights and original character of the zamindars. There can be no doubt, that, in the most ancient time of Hindoo history, the property of the land was vested in the sovereign, and the opinion that the zamindars were merely collectors of the revenue, seems the more probable. Indeed there is a common saying among the Mah-rattas, that "the daughter belongs to her parents, but the land to the king."

Our most accurate source of information on the subject of the tenure of land in Hindostan, before the arival of the Mahomedan conquerors, is derived from the Institutes of Menou: these were drawn up about 1300 years before Christ. In these Institutes, there are very minute and particular regulations on the subject of the rent of land, from which it appears, that the sovereign in most parts was the proprietor. The medium rent was estimated at a sixth part of its produce; but it varied considerably according to the degree and quantity of labour which the nature of the soil and other circumstances required. If the lands were very unproductive, and necessarily required a very considerable degree of labour, only an eighth or a twelfth of the produce was
A is—

The produce of the crop was ascertained as nearly as possible before the harvest commenced, in the presence of the inhabitants of the village, by skilful and impartial persons, who, in the adjustment of their business, were materially aided by a reference to the produce of former years, as recorded by the accountant of the village. As these persons were appointed by the collectors of the rent for government, it was in the power of the Ryots, if they were not satisfied with the estimate of the crop, to make another survey by people of their own choice; and if the estimates differed much, a third survey was made under the direction of the village officers. The share of the cultivator was greatest on the plantation or garden culture, on account of the very great labour in the management, and the distance and hazard of carrying the produce to market. The rent of this land, as well as that levied on the small grains, was always paid in money, and was fixed. Those lands which required artificial means to water them, paid a smaller portion of rent than those which were fertilized by the periclitical rains.

There were, however, certain portions of land attached to each village, which paid no rent to the sovereign, or only a very low rent. These were small allotments for the support of the Pagoda Establishment and their priests; for charitable uses, such as keeping up the choutis for the accommodation of travellers; and for the support of the Brahmins and bards. After the Mahomedan conquest, allotments of land were also for the support of their temples, burying-places, and monks, and for furnishing the lights which it is customary to burn at Mahomedan tombs. The local officers of government had also allotments of rent-free lands. But the allotment to the different village servants was most characteristic of the ancient Hindoo constitution, and therefore requires to be particularly noticed. It is thus described in the Fifth Report on the Affairs of the East India Company, already referred to: "A village, geographically considered, is a tract of country comprising some hundreds or thousands of acres of arable and waste land. Politically, it is a corporation or township. Its proper establishment of officers and servants consists of the following descriptions: The Potail, or head inhabitant, who has the general superintendence of the affairs of the village, settles the disputes of the inhabitants, attends to the police, and performs the duty of collecting the duties within his village. The Curman, who keeps the accounts of cultivation, and registers every thing connected with it. The Tallier and Totic; the duty of the former appearing to consist in gaining information of crimes and offences, and in escorting and protecting persons travelling from one village to another; the province of the latter appearing to be more immediately confined to the village, consisting, among other duties, in guarding the crops and assisting in measuring them. The boundary-man, who preserves the limits of the village, or gives evidence respecting them in cases of dispute. The superintendent of the tanks and water-course distributes the water for the purposes of agriculture. The Brahmin, who performs the village worship. The schoolmaster, who is seen teaching the children in the villages to read and write in the sand. The Calendar Brahmin, or astrologer, who proclaims the lucky or unlucky periods for sowing or threshing. The smith and the carpenter, who manufacture the implements of agriculture, and build the dwelling of the Ryot. The potman, or potter. The washer-man. The barber. The cow-keeper, who looks after the cattle. The doctor. The dancing-girl, who attends at rejoicings. The musician and the poet."—Such was the establishment of a village in all parts of Hindostan during the independence of the native Hindoo governments, and such it is at present in some parts. To all the members of this establishment a certain portion of land was allotted, according to their rank and the importance of their duties. Besides these allotments to them, the Pagoda establishment, the choutis, the local officers of government, &c. they were each entitled to certain small shares of the crops of the village, which were set apart for them previously to the division of the produce between the sovereign and the cultivator. The Mahomedans also made large grants of land, under the name of Saghires, to such officers as were high in civil and military rank.

The most probable opinion, as we have before stated, is, that the zemindars were only the collectors of the revenue; but in process of time, taking advantage of the weak and unsettled state of the Hindoo governments, they claimed and exercised all the rights of absolute power over the land. In this character, the British government have deemed it prudent, and a matter of policy, to recognise them.

One of the principal and favourite objects with the Emperor Aabar, was to make a survey of the whole lands of his empire. After this was done, he fixed the land rent at a fourth part of the valued produce, which they deemed equal to a half of the produce if taken in kind. Only one-fourth was taken from garden produce. For the purpose of carrying this plan of revenue into effect, an officer was appointed to reside in every village, whose duty it was to inquire into the receipts and disbursements of the Ryot, and another officer who was bound to protect the Ryot against the injustice of the zemindars or collectors. In order to understand the reason of the appointment of the first officer, it is proper to remark that, in the time of Aabar, as well as at present, in most parts of Hindostan, a system similar to that of the métayer system of France prevailed. The Emperor also caused regular rent-rates to be made out and keeped by the officer whose duty it was to protect the interests of the Ryot. In short, he revived the ancient system of the Hindoos with regard to landed property. It deserves to be noticed, that the term zemindar occurs only twice in the institutes of Aabar.

Having thus given a general account of the nature and tenure of landed property as it existed during the most early periods of Hindoo history, and as it was revived by the Emperor Aabar, it may be proper to describe it as it exists at present in different parts of Hindostan. In Bengal a large portion of the landed property is held by the zemindars, and the zemindaries are very extensive. The zemindary of Barduan comprises nearly 3,280 miles, being about 73 miles long, and 45 broad. This, however, is in fact the property of government, as the Rajah who holds it pays a very high rent for it. The zemindary of Haugeshy comprehends 18,009 square miles. In Bahar the zemindaries are comparatively small, there being but three principal zemindars. The most ancient zemindary in
this part of Hindostan is that of Bissunpoor, in the Burdwan district of Bengal. It appears from good authority to have been in possession of the present proprietor's family for upwards of 1100 years, the present zamindar having a list of 56 successive Rajas who held it in regular succession. Its area comprises 1236 square miles.

When the Northern Circars were acquired by the British, they consisted of zamindary lands and haveli lands. The former were situated in the hill country, and in the plains between the hills and the sea. The zamindars who possessed them were surrounded by military tenants, who held their lands on the feudal tenure of personal service. The latter not being so well secured by the nature of the country, seem to have been more quiet, and more disposed to encourage agriculture; accordingly they farmed their lands to the Ryots, on annual or longer leases, for rent paid either in kind or money; one or more villages or districts, and sometimes entire zamindaries, were thus leased out.

The haveli lands consisted of the demesne lands of the Circar or government; they constituted a large portion of the northern Circars. After the usual deductions were made from the crops of these lands for the Pagodas, &c. the government possessed the right to certain proportions of the remainder. But in order to obtain this proportion with the least trouble, a whole Circar was rented to one individual; the more ancient custom, however, was to let the land in smaller portions.

In the Jaghire, there were lands held as inheritance from father to son, called mehrass lands, and lands held by the pyacarries, or subtenants. For some time, it was matter of doubt whether the mehrassadars had a proprietary right in the soil or not; but this question was set to rest by Mr. Place in the year 1799, who proved that they possessed this right originally derived from the sovereign, to whom they paid a certain proportion of the produce, as the tenure on which they held their land; that they could sell, mortgage, and bequeath their lands; and that, until the period of the Mahomedian conquest, they were described, in the Malabar language, by the term Caniatchy, compounded of cani, land, and echy, heritage. The pyacarries, who were called strangers by the mehrassadars, under whom they held their lands, seem to have had a life-property in them, receiving, however, only about 45 per cent. of the produce. Such were the resident pyacarries; but there were other pyacarries, who seem to have had mehrass lands in one village, and to have taken lands on liferent, or sometimes only from year to year, in another. These pyacarries were allowed 50 per cent. of the produce.

In the provinces of Canara and Malabar, the tenure of lands is very ancient, and is clearly pointed out by a series of regular deeds, which have a very striking resemblance in both these provinces. Land formed a clear private property, more independent and perfect in its tenure than even in England, and it still remains so. It is possessed either by a single individual, or by a number in partnership, each of whom possesses an equally inalienable right in the estate. In Canara there are three kinds of occupiers; those who hold under the nair mul guerry tenure; under the shud mul property tenure; and the chalic guerryes. The land held under the first tenure descends to the heirs-at-law, and is inalienable. In cases of the non-payment of taxes, or of mortgage, it reverts to the owner as soon as he satisfies government, or the Mutgolle. Under this tenure, land is not even forfeited, where the owner's life is taken away by the laws of the country, but passes immediately to the heir-at-law. On the failure of heirs it reverts to government; but is always granted to individuals on the payment of a few years' rent. In some instances the proprietors hold immediately off the government; but their proprietary rights are not in the smallest degree lessened by this circumstance. The shud mul guerryes, or tenants for ever, are in fact lesser proprietors, holding under those just described; they can, however, give up their lands to the latter, who are bound to reimburse them for the improvements they have made; and in case the tenants for ever die without heirs, their lands revert to the superior landlord. Chalic guerryes are tenants at will, who hold under the lesser proprietors. The tenants for ever, as well as the tenants at will, pay a fixed rent either in money or in grain; and never by a share of the crop, as in the other parts of the British possessions in India, where fixed rents exist.

Private property in land in Malabar, where it has rested, from the most remote times, on a tenure as well defined, extensive, and secure, as in Canara, is called jumman, a word which signifies birthright. In one respect, indeed, these lands differ from the lands of the greater proprietors in this latter province; for in Malabar they may become forfeited by acts of treason to the sovereign. In the event of the proprietor having no legal heirs, he possesses the right of adoption, which prevents his land from escheating to the government. In mortgaging lands in Malabar, there are some peculiarities. The proprietor receives from the mortgagee two thirds of the produce or rent of the estate, and retaining an interest in the land itself; when he loses this interest, he ceases to be a proprietor. There are two other modes of transferring land, which, however, are very little different from that just described. In all cases the mortgagee accounts to the proprietor for the surplus of rent above the interest to which he is entitled. If the proprietor is under the necessity of raising further sums on his land, there are other forms of debt estiablished by the custom and laws of the country, by which he alienates so much more of his proprietary right; and, in many instances, the money advanced on mortgage bears a value so nearly equal to that of the estate, that the proprietor at length "has nothing left him but a handful of rice, or a measure of grain," as an acknowledgment of his title. In some parts of Malabar the option of redemption is in the mortgagee; in others, in the proprietor. Where the former has a right to refuse the redemption, and has long been in possession, there is another species of contract, by which the land is transferred to the mortgagee as a kind of freehold. All these kinds of contract must be executed previously to the execution of the deed called attiper, by which the proprietor absolutely transfers his property. There are several descriptions of tenure by which lands are granted in lease. According to one of them, the proprietor receives a sum of money in addition to his rent; the tenant retaining so much of the latter as will cover the interest of the money advanced. Under another kind of lease-hold tenure, the interest of the money and the rent are considered security for each other. Lands are also let for a number of years for a gross sum advanced by the tenant, who pays duty to the farm. In those cases in which the land requires improvement, the tenant binds himself to improve it,
particularly to inclose it with mud-walls, and plant it with productive trees, and erect the necessary buildings upon it; and the proprietor, in consideration of those improvements, grants a lease for a certain number of years, which, however, is generally extended if the tenant has fulfilled his contract. The buildings and plantations are so far the property of the tenant that he is at liberty to mortgage them. There is also a simple lease, when the rent is annual or for a definite term. The general price of land is 20 years' purchase. As the Hindu law requires that property should descend to all the male children of a family, and admits adoption, it is evident that land would be, in the course of time, divided and subdivided into portions not worth possessing, were not some measure adopted to control the law. Accordingly, it is the general practice through the Peninsula to preserve the original property nominally entire as long as possible, by letting it stand in the names of those who have the greatest shares in it. They manage it for the rest, each receiving his portion of the grain it yields. The various tenures which we have described, exist in the greatest purity in the southern provinces of the Peninsula, situated below the Ghauts, which were last invaded; and it is on this account, as exhibiting the most genuine view of the tenure of landed property among the Hindus, that we have dwelt thus long on the state of landed property in Coon and Malabar. It is no more evident in the history of the Hindus, from the reign of their first princes till the downfall of the Hindoo sovereignty, that any of the landed rights which have been enumerated and described, were ever, in the smallest degree, impaired or ever questioned.

Besides, however, these tenures in this part of India, which, it will be observed, are entirely exempt from the claims or control of zamindars, there were lands held by Polygars, who, in many respects, resemble the zamindars of the Northern Circars. The Polygar's territory, as it is called, is situated principally between the 10th and 11th degrees of latitude, and is bounded on the east by Tanjore and the sea, and on the west by Dindigul. The origin of the proprietary rights and power of the Polygars may be traced to the same causes which produced the zamindars of the Northern Circars. They were, in fact, military chieftains, who obtained their power and landed property by force, and preserved it by the numbers and strength of their vassals. The inferior, or lower, caste of this Polygar country of Mysore, three descriptions: the first consisted of those who were paid entirely in money; the second, of those who possessed lands on service-tenure, but who, being also farmers of other lands, seldom regarded their service-lands as of much consequence; the third description consisted of such as confined themselves to the cultivation of their service-lands. These vassals were called peons; and the common allowance of a common peon was a field valued at the rent of 6 pagodas. The head peon, who could bring in 10, 50, or 100 common peons, had a piece of land of from 9 to 24 pagodas rent.

In the Tinnevelly district, there are three kinds of tenure, viz. villages, of which the absolute proprietary right is chiefly held by Brahmins; villages, of which the absolute proprietary right is chiefly held by soodras; and thirdly, villages, which having gone to waste, Soodra inhabitants were invited to occupy and cultivate them. The lands under the first tenure, though nominally vested in the Brahmins, in fact belong to all the inhabitants of the village; and no transfer is rated that is not approved and sanctioned by every one of them. At stated periods, a new division of these lands take place by a kind of lottery; the object of which seems to be, in the first place, to prevent any proprietor's right being established to any particular spot; and, secondly, to afford every inhabitant the chance of occupying the fertile as well as the less fertile parts of the land. The villages under the second kind of tenure, resemble those under the first, except that in the former, the influence of the Brahmin predominates, who will not permit the soodra to interfere in his village. The last kind of tenure comprises all those lands which the inhabitants are not considered at liberty to sell; they form a large proportion of the district, and are generally occupied by the soodras. The land of each individual is fixed, there being no new distribution of it at any time. Each Ryt cultivates his own land as long as he possesses the means; if these fail him, he mortgages his right of cultivation till he regains the means. When the supply of water is deficient, all the inhabitants assemble, and having determined the extent of land that may be cultivated, according to the quantity of water in the tanks, &c., apportion it out to each, with reference to the extent of land he holds.

In Tanjore, there are also three descriptions of tenures by which landed property is held in most parts of Hindostan: they are all comprised under the term potlach tenure, or tenure of hereditary possession. There are other lands, however, denominated cost and comar lands. The former are very extensive in some parts of India, consisting of such lands, as having been neglected, or entirely depopulated, in consequence of the oppression of the collectors, are under the immediate superintendence of the government. The comar lands are also very common; they consist of such, as having no native tenants, are cultivated by contract; the zamindar ordaining to the cultivator the necessary capital, and receiving an equal share of the crop, as well as interest for the money advanced.

By the act of perpetual settlement, as it is called, the East India Company not only confirmed the zamindars in their proprietary right to the land, on condition of paying the value of a certain part of the produce, but they also fixed the rent to be paid in kind by the Rytas. In no other respect have they interfered with the landed tenure of India.

In the preceding illustrations, the rent of land has been stated generally to be a certain part of the produce, paid either in kind or in money. In those parts of Hindostan where agriculture flourishes most, the average rent of wheat land, calculated by the stipulated portion of the average produce, taken at an average price, is about 19s. the English acre. The rent of sandy loams, which can be irrigated with little trouble or ex-
The agriculture of Hindostan, generally speaking, is
in a very rude and imperfect state. There are, how-
ever, districts in which this art has reached a state of
improvement, not inferior to that in which it exists
in many parts of Europe. Perhaps the Bardwan district
of Bengal deserves the first place in the scale of agricultural
excellence; and the province of Tanjore, the second. Many
parts of the province of Allahabad, and especially the
district of Benares, rank nearly on a level with Bard-
wan and Tanjore. In the neighbourhood of the city of
Patna, the capital of Bahar, also, the husbandry is ex-
cellent; the fields in many places being cultivated with
such nice and minute attention, as to resemble gardens.
Travancore is distinguished for its excellence in what
is called the wet cultivation, which is carried to such a
degree of successful perfection, that the whole of the
government expenses, civil, military, and religious, are
defrayed from it alone, without drawing any thing from
the produce of the dry-land cultivation. The agricul-
ture of the Circars is also good. From this province
and Tanjore, the Carnatic is frequently supplied with
rice; the Circars being esteemed its granary during
the north-easterly monsoon, and Tanjore during the
south-west monsoon. Formerly the Punjab exhibited
undoubted proofs of good husbandry, and its crops, ow-
ing to this and the natural fertility of its soil, were
always large; but the consequence of the devastation it has
sustained, and the number of petty hostile states into
which it is divided, it is now but very imperfectly cul-
tivated, and contains a large proportion of land abso-
lutely waste and neglected. That part of Agra which
is called the Doab, was formerly, like the Punjab, cul-
tivated with skill and success, especially during the lat-
ter part of the Nabob of Oude's government. While it
was under the management of Aimmass Ali Khan, and at
present, its cultivation is improving, as indeed is the
case with all those parts of India which are placed un-
der the British authority. In the Middnapoor district
of the province of Orissa, improvements have lately ta-
ken place in agriculture; but they arise rather from the
extreme ease with which they may be made, than from
the superior information or activity of the inhabitants.
The other parts of the Decan in which the agriculture
risers above the level of that generally practised in Hin-
dostan, are the low districts of Aurungabad, some parts
of Berar, and the Circars, already mentioned. In the
south of India, besides Tanjore and Travancore, which
rank in the highest class, the industry of the husband-
man in the ceded districts has raised the agriculture of
this province to a considerable degree of perfection;
and they are likely soon itself to improve, in conse-
quence of the excellent regulations introduced by the
British. In no part of India has the husbandman been
obliged to struggle with greater difficulties in the im-
provement of his land, and nowhere has he surmounted
them more completely than in Canara. The largest
portion of the surface of this province is so rocky and
uneven, that nearly all the agricultural labour, and es-
pecially the indispensable previous operation of level-
ling the ground, must be performed without the aid of
cattle; which, indeed, are by no means common. And,
even after the land is brought into a state of cultivation,
it would soon revert to its original character, and be
broken up by the torrents from the mountains, were not
the husbandman constantly alert and active. Notwith-
standing these difficulties, there everywhere appears un-
doubted proofs of good husbandry, not merely in the
quantity produced, but also in the neatness of the cul-
ture, and the regularity and method with which it is
carried on. This may in a great degree arise from the
circumstance, that each man cultivates his own land,
however small; all the land here, as has been already
remarked, being private property, and the subdivisions
of that property being very minute. The same charac-
ter applies to the husbandry of the province of Malabar;
each proprietor bestowing on his little spot "all that
minute labour and attention which is so important to
Indian husbandry." In no province of the south of In-
dia was the husbandry worse than in Barramahal, pre-
viously to the introduction of the permanent settlement,
but at present it is very respectable, and will probably
improve. The tract of land in North Coimbeetor, which
lies near Mutu and Calegaha, and that part of South
Coimbeetor which stretches along the banks of the
Amnawati, are remarkably well cultivated, particularly
the first district, in which the management of rice is
equal to that of any other part of India. The same
character applies to the rice cultivation in the valleys of
Cochin. From this sketch of the general state of agri-
culture in Hindostan, it will be seen, that, with a few
exceptions, that of the south of India is superior to that
of Hindostan Proper; that it is more generally good,
and that the husbandry of the Decan is inferior both to
that of Hindostan Proper and the south of India.

Over all Hindostan, as in every country that lies
within the tropics, or only a little beyond them, the
general mode of cultivation, as well as the particular
crops cultivated, must depend, in a great measure, on
the more or less abundant and regular supply of wa-
ter. Hence arise two distinct modes of cultivation in
Hindostan, besides subdivisions of these modes. The
two leading species of cultivation are denominated
nunjah and punjah; the first being the wet-grain cul-
ture, and the other the dry-grain culture. The first is
more attended to than the second, and is deemed more
valuable and beneficial. The grain cultivated on nun-
jah lands is generally only of one kind, or at most of
two, and is consequently cut down at one season or two;
hence the produce of this land can be stored, watched,
and sold, with much greater facility, and at much less
price, than the other kinds of grain. In the south of
India, the produce of nunjah land was always divided
between the government and the cultivator. Punjab land
is in almost every respect the re-
spective of this. The grain sown on this land are very
numerous, and are put into the ground at various periods:
the produce is uncertain, depending on the rain that
falls. The gathering of the crop must be performed at different times. That part of it which carries the grain in the ears must be reaped at one season, and that which carries it in the pod at another. It happens that several kinds are sown together, in the same field, each ripening at a different period; and if one of these be cotton, which is often the case, it must be gathered every day after the plant arrives at full growth. Hence, the produce being uncertain, and the labour great, the revenue exacted by government from punghah land is uniformly paid in money. This kind of land appears to have been brought into cultivation after the punghah land, as it generally lies at a considerable distance from the village.

Punghah mail punghah, is a species of punghah cultivation, carried on either in the stubble of paddy or punghah land, or when, from an accidental deficiency of water, land which is usually cultivated with rice becomes unfit for that grain; in these cases, the cultivator, availing himself of the moisture remaining in the ground, or of the water that may be drawn by picoatas to the field, sows the best kinds of dry grain. Panypur, or typical lands, are lands managed according to the garden culture, in which the more valuable articles, such as sugar cane, tobacco, chillies, &c. are grown. These lands are generally secured against a failure of water by artificial means.

The punghah lands are rendered fit for wet-grain cultivation, by the overflowing of the rivers,—by canals and water-courses cut from the rivers and streams, for the purpose of irrigating them,—or by water drawn from tanks and wells.

1. The Ganges and its branches are the great sources of fertility to that vast tract of country which lies near their banks, in Hindostan proper. In consequence of the rains which fall in the mountains whence it springs, this river begins to overflow its banks in the low country in the month of April. Its rise is at first gradual; but as soon as the rainy season has reached the low country, and becomes general, it rises with great rapidity. “By the latter end of July, all the lower parts of Bengal are overflowed contiguous to the Ganges and Brahmapootra, and form an inundation of more than 100 miles in width.” By the middle of August, the river has increased upwards of 14 feet at Dala, and 22 feet at Jellingly, in common years. As soon as the rainy season ceases in the mountains, which is about the middle of Aug., has ceased, the Ganges begins to decrease in Bengal, slowly at first, like its rise, till the rains cease also in this province. It is easy to perceive, that this periodical increase of the Ganges must not only have formed the rich alluvial soil of this part of Hindostan, and must every year deposit on it materials which will serve to keep up its fertility, but must also prepare the ground for those crops which require on it cultivation, and even for those which would not thrive and repay the husbandman in a climate so hot, and at other seasons so very dry, if these inundations did not take place. Accordingly the rise of the Ganges is watched with great attention and anxiety by all the inhabitants of the country through which it flows, since scarcity or famine are the consequences of a failure or a great deficiency of its inundation. If, on the other hand, its inundation is unusually great, the corn may be swept away and destroyed; but this evil is generally light and partial, compared with the calamity which results from a deficient inundation. The Ganges, without the assistance of art, waters immense tracts of land, and renders them fit for the wet cultivation. In former times, as we have already noticed, canals were made for the purpose of conveying the waters of the Indus to irrigate the lands, as well as for the purpose of internal communication; and a canal was made from the Jumna to Delhi, which was probably used, though not principally constructed, for the benefit of agriculture. But neither in those times, nor at present, has all that advantage been taken of either of these rivers, particularly of the Ganges, which agriculture might derive from them.

The Punjab, or that extensive tract of country which is watered by the eastern branches of the Indus, is not entirely inundated and enriched by this river: The lower part only, towards Mulpan, which is very flat, deriving this benefit to its agriculture from the periodical rains which fall between the months of May and October. The lower part of the province of Sind is also inundated by the Indus. Every where also this river and its branches do not, unassisted by art, greatly or extensively benefit agriculture.

2. Though artificial inundation from the Ganges is by canals not carried to such extent, nor conducted with so much water as it might be, it is not entirely neglected. In the Rohilcund territory especially, the waters of this river, or rather of the Jumna, the Ganges, and other smaller streams, which flow into it, and intersect this district, are distributed over its surface by means of canals. But as the soil in every part of the country through which the Ganges flows is naturally rich and loamy, the inhabitants are not placed under such an absolute necessity of having recourse to irrigation, as those who live on the sandy and parched soil of the lower parts of the province of Sind. Accordingly, in this province, considerable attention is paid to irrigation by means of canals and water-courses. A regular system is pursued, and a fixed tax levied by government for the construction and repair of these water-courses. Every bigha of land, (one-third of an acre,) pays a revenue of 1¼ to 3¼ rupees for the water with which it is supplied by a canal or wheel. One wheel is capable of watering 16 bighas. It is in the south of India, however, that the practice of rendering land fit for the wet cultivation, by means of canals and water-courses, is carried on to the greatest extent, and with the most industry, skill, and success. In the province of Coimbatore, there is a canal from the river Ilausani, constructed on the best principles, as well as executed with considerable judgment, which waters a narrow space of ground, 15 Malabar hours journey in length, and has raised the rent, and increased the produce of the land adjacent very much. In the vicinity of Serangapatam there are many excellent canals, which are drawn from the river Cavery along the windings of the hills; the intermediate spaces between these canals is watered by branches. The water of the Cavery is forced into the main branches by means of dams thrown across it, which are formed of large blocks of granite. The whole must have been executed at great expense, and is a work of very great labour and strength. The river, whence these canals are drawn, is made nearer the sea, to answer still more important and beneficial purposes to agriculture; for it is in consequence of the water-courses sent off from it through the Tanjore, to this province is entitled to the second rank, among all the provinces of Hindostan, for agriculture. It has already been stated, in our account of that river, that, opposite to Trichinopoly in the Carnatic, the Cavery divides into...
two branches; which, about 13 miles to the eastward of
the point of separation, again approach; the northern
branch, however, being at this place 20 feet lower than
the southern; and that an immense mound is formed,
to prevent the waters of the one branch from descen
ding into those of the other. The higher, or southern,
branch retains the name of the Cavery. From it canals
are conducted in all directions; "which, by means of
embankments and reservoirs, are directed into every
field, and fertilize a tract of country, from Dericotta
to Point Calymer, (a distance of nearly 70 miles,) which
would otherwise remain a barren sand." In most
parts of the Carnatic, the water necessary for the purposes of
wet cultivation is supplied from tanks. In the Vellore
district of this province, however, the system of canals
is followed. These are dugs, during the dry season,
across the channel of the rivers, below which, even
at this period, moisture is always met with; or they
are drawn from subterranean streams, many of which exist
in this tract, and contribute not a little to the greater
degree of verdure which prevails here than is usually
seen in the Decan or in the Carnatic.

3. Tanks, or reservoirs of water, are of two kinds in
Hindostan. They are constructed either by digging,
or by shutting up, by an artificial tank, an opening be
tween two natural sides of hills. The former mode is
practised in Bengal, and in other parts where the sur
face is level, and the soil loose, and free of rocks; the
latter, in the more hilly districts of the Decan and the
south of India, where natural situations, proper for this
kind, are met with in abundance, and where the former
kind could not be constructed without almost infinite
labour and expense. Considerable insecurity, as well
as great labour, are requisite in the formation of the
tanks in the hilly districts; in the selection and damming
up of the outlets of the narrow valleys; and in making
the surrounding rocks answer effectually the purposes
of walls. In Bengal, and the other flat districts, the
tanks are generally lined with stone, and their bottoms
rendered hard, and impervious to the water, by a mix
ture of chunum and clay. In these parts of Hindostan
they frequently cover 100 acres of land. Tanks are
constructed either by government, or by rich individu
als. In the former case, the tax is levied on the land
for their repairs; in the latter, they are kept in repair
by the person who constructs them, but, as a compen
sation, one-fourth part of the lands which receive water
from the tanks is given up to him in full proprietary
right.

Tanks are very numerous, and some of them very ex
tensive in the Carnatic; where, indeed, from the ext
reme aridness of the soil, and the want of water from
other sources, they are indispensably necessary to cul
tivation. Some of them occupy an area of eight miles in
length, and three in breadth, and contain water enough
to supply the lands of 32 villages for 18 months. In
the villages watered by one tank, there are 5000 persons
employed in agriculture; and at another place, there is
a tank which waters 2500 acres. These tanks are made
either in the manner already described, or by inclosing
dry and low situations with a strong mound of earth.
Tanks are also constructed in many parts of Hindostan,
at great labour and expense, not only for domestic
purposes, but also for irrigating the land. In the ele
vated and sandy districts of Ajneer, the tanks are from
100 to 200 feet deep, made of brick. In Guzerat, there
are a greater number of tanks. One is said to have cost
nine lacks of rupees; and another is remarkable for its
antiquity; appearing, from the inscription, to have been
erected in the year 1482. In the sandy soil of this pro
vince, which lies to the north of the river Mahi, the
tanks are from 80 to 100 feet deep; but in the adjoining
province of Malwa they are still deeper; the inhab
itants being frequently under the necessity of digg
ing to the depth of 300 feet before they obtain a suffi
cient supply of water.

The machine used to draw water from the wells to
irrigate the fields, is called a picotah, and is thus de
scribed by Somersat: "It is a slide erected on the side
of a well, or reservoir for the rain water, to draw up
the water, and afterwards to conduct it at pleasure.
This machine, equally simple and convenient, is con
structed in the following manner: near the well a piece of wood is fixed, forked at the top; in this fork
another piece of wood is fixed to form a slide, which
is formed by a peg; and steps cut at the bottom, that
the person who works the machine may easily get up
and down. Commonly the lower part of the slide is
the trunk of a large tree. To the upper part is fixed a
pole, at the end of which hangs a leather bucket. A
man gets up the steps to the top of the slide, in sup
porting himself by a bamboo screen, erected by the
side of the machine; he plunges the bucket into the
well, after which he descends, and by his weight draws
up the bucket. Another man attends to pour into the
basin, from whence the water flows into the furrow, and
is distributed over the whole field. The person who
empties the bucket sings, to encourage himself, one,
two, three, according to the number he has emptied.
When the water in the tank is on a level with the sur
face of the earth, they use a basket for watering, which
is made impenetrable by cow-dung and clay; and is
suspected by four cords. Two men hold a cord in
each hand, draw up the water, and empty it in balan
cing the basket." (H. 192.)

34. Land under watercourses is more productive than
land under tanks or wells, in the proportion, in land of
the first quality, of 146 to 97; in land of the second
quality, of 119 to 86; and in land of the third quality,
of 97 to 75.

The dreadful consequences which follow a deficiency
of moisture, have often been experienced in Hindostan;
and the apprehension of these consequences induces the
inhabitants to be so extremely anxious respecting the
overflowing of the rivers, and the erection of tanks and
wells. In Surat, and the neighbouring counties, there
was a dreadful famine in the year 1630. In the year
1661, the famine was almost general throughout the
Mogul empire; but the most destructive was that
which occurred in Bengal in the year 1770. The crops
of December 1768, and August 1769, were both scanty,
and hardly a drop of rain fell in October 1769,
which caused an almost total failure of the third crop
of rice. The refreshing showers which usually fall be
tween January and May, and in which the interme
diate crops of inferior grain depend, also failed: the
heat was insufferable. Upper India suffered nearly in
an equal degree with Bengal, and consequently could
not send any supply of rice. Famine began to ap
pear in November 1769, and before the end of April
1770, rice rose to ten prices, and even then could scarcely be had: the roads and streets were filled with the dead and dying; the inhabitants fed on forbidden and abhorred animals; the child on its dead parent, the mother on her child. The number who died in Bengal at this period may be estimated at three millions. In the same year nearly one half of the Middnapoor district of Orissa were swept away by famine. The coast of Coromandel, perhaps, suffers more frequently under this calamity than most other parts of India; and in an especial manner the Carnatic, in consequence of its sultry climate, sandy soil, and irregular and inadequate supply of water.

In India, the ground under the wet cultivation brings forth crops almost all the year round; the first crop of rice is gathered in about the end of August, the second, which is the greatest, early in the end of April. Even on land which is not under the wet cultivation, there are two harvests. Kleriaf, in September and October, and Rubbeef in March and April. In the province of Agra, the following are the principal articles produced in the spring harvest. Wheat, vetches, barley, adas, a species of lentil, linseed, messer, azewara, a kind of millet, mustard, pea, fenugreek, shaly-kour, a particular kind of rice; pot herbs, ayewain, an inferior kind of onion-seed, onions, carrots. In the Autumn harvest, common sugar-cane, shaly muskur, common rice, mash, mowing javar, a kind of pea, shamath, a grain resembling poppy seed; gall, a grain resembling mustard; hedrisusa, sesame, a grain of which oil is made; turreyah, a small grain resembling mustard; turmeric, water melons, pot-herbs, morch, linderah, azran, a kind of millet, korre, indigo, cotton. The average produce of the spring harvest is about three maunds one seer; a maund is about 74 lbs. and a half; and a seer nearly 2 lbs.; and the average produce of the autumn harvest is about 5 maunds 6 seers per bejah. This is about the common produce of land in the Company's service. Hence it appears that the produce of the two harvests is about 28 maunds, 24 seers per acre, or nearly four quarters. Besides the grain, &c. above enumeratad, there are cultivated on those lands which have a regular spring and autumn harvest, bhootsh, which flowers in July, and is reaped in August and September; congoe, panicum italicum, which flowers the end of July; murhia, the raggy of Mysore, natchey in the Carnatic, and maud or mal, in the upper provinces; cynosurus coracens; bagira, holcus spicatus, this is reaped in both harvests; herbzera, a species of panicume, these belong to the autumn harvest. In the spring harvest, chamnna, cerea arsiminum; tory, or arber, cythamus cajan; this is sown during the rains mixed with the javar; and when that crop is reaped, it stands till the wheat harvest.

It will be seen from this account of the different kinds of produce in the spring and autumn harvests, that in the latter are reaped most of the European grains. As it would carry us far beyond our limits, we shall, in our further notice of the agricultura of Hindostan, confine ourselves to such articles as are known in Europe, beginning with those which are most generally cultivated in that quarter of the world.

Wheat is principally cultivated in Hindostan Proper, and in one or two provinces of the Decan; but the climate to the south of the Decan is much too hot for it; nor, indeed, is there much demand for it, in consequence of rice being the favourite and almost universal food of all classes in Hindostan. From Allahabad to the frontiers on the north, wheat is the principle object of the farmer's attention. It is sown on the sandy loams, which are ploughed once about the commencement of the rainy season in June. After the rain ceases, it is ploughed repeatedly again, sometimes fifteen times. In September or October it is sown. When the dry season begins, it must be watered; it requires four bullocks and three men to water an acre in nine days. The average crop is estimated at fifteen maunds per bejah, or seven quarters per acre. In the Benaes district of Allahabad, the Ryots, or husbandmen, are very industrious in the labour they bestow on their wheat and other crops. It is not unusual for them to plough by moonlight, and for some crops they plough the land forty times. Barley, peas, oil cakes, and a plant affording a yellow dye, are often mixed with the wheat in Allahabad: the last is generally planted at the distance of six or ten feet. The wheat of the province of Bahar, especially that part of it which is watered by the Ganges, Soane, &c. is of a superior quality to that which is usually grown in India: that perhaps of the worst quality is grown in the Dinapore district of Bengal. The flour produced from it is very dark, and scarcely saleable among Europeans. Gutarat is famous not only for the quantity, but also the quality of the wheat it produces, especially on the rich black soil near Wurgaum. From this province the Europeans in Bombay are principally supplied with wheat. Barley is a most abundant crop in all the upper districts of India, where it is made into thin cakes by the natives. March and April are the harvest months for wheat, barley, and the grains, &c. which are almost always sown in the same field with them. As there is a very great and almost universal demand for vegetable oil among the natives of Hindostan, such plants as produce it are cultivated most abundantly in both harvests, mixed with other crops. Flax and mustard are generally sown along with wheat and barley for this purpose; and as they ripen first, they are pulled from among the wheat and barley. The latter are reaped together; but are necessarily much injured by pulling out the flax and mustard, and still more so when the plant affording the yellow dye is sown in the same field. The produce of these grains is also diminished by their being often permitted to stand till they are over-ripe. In some parts of Hindostan Proper, where pasture for cattle is scarce and bad, the wheat and barley straw will sell for as much as will pay the rent.

Rice is cultivated much more extensively than any other crop in India: indeed there are very few provinces in which it is not the most prevalent crop. There seem to be three kinds of it in the south of India: the first is reaped in September; the second in December and January; and the third in March or April. But in most parts of India there are only two kinds; the common rice, and that kind of which the grains are very white and small, with an excellent aromatic taste. There are three modes of sowing this grain practised throughout India generally. According to one mode, the seed is sown dry on the fields which are to bring it culminating to maturity: this is called the dry seed cultivation. By the second mode, the seed is steeped in water till it germinates, and the field in which it is to be sown is watered till it becomes a kind of puddle: this is the sprouted cultivation. The last mode is by transplantation. A piece of rich ground is selected, in which the seed is sown; and as soon as the plants have attained the height of a foot they are transplanted. The means used to sink it to the bottom of the field, which is covered with water, are very simple and effectual.
The first mode is necessarily confined to the higher grounds; the other modes are followed on such lands as lie low, and can be easily watered. The Ryot is determined with respect to his time of sowing rice, by observing its natural seasons. In a wild state, it sows itself in the first month of winter, and at the approach of spring begins to appear above the ground: it ripens during the rainy season, and drops its seed at the beginning of winter. But, in order that he may have two crops of this necessary and valuable grain, the Ryot sows it not only at its natural period of vegetation, but also during the second month of the rainy season, that he may reap a second harvest at the beginning of winter. In those parts of Hindostan Proper, where rice is cultivated on good land, well managed, five quarters per acre is the quantity of the produce, or a return of fifteen for one on the seed. In some parts of Mysore, the first quality of land will produce from 47 to 49 bushels; the second from 35 to 42; and the third from 17 to 24 bushels of rice. Two crops of this grain are very seldom grown on the same field in one year. In the northern parts of the province of Cochin, however, the rice grounds, which lie in narrow vallies extremely well watered, enable the cultivators to raise two crops annually on them. This is also the case upon land of the best quality in the Runghpoor district of Bengal; two crops of rice being obtained in the year, besides an intermediate one of mustard seed. In the Vellore district of the province of Malabar, there are a few remarkable spots of land, watered by perennial streams, which produce three crops of rice annually.

Where it is necessary to use artificial means to water the rice, the rice fields are divided into squares of 100 or 120 yards, round the sides of which there are borders so high and firmly constructed as to keep in a sufficient quantity of water; furrows are made from one square to another, by which the water is, without much labour, carried all over the rice field. At harvest, it is cut with a sickle; nearly four feet of the straw is left on the ground, in order that it may rot and serve as manure. It is made into sheaves, which are beat on the ground as a substitute for threshing; but as all the grain cannot thus be got out, the sheaves are again beaten with a bamboo to obtain the remainder. Rice is cleaned with a wooden pestle and mortar; and this operation, like all the other operations connected with husbandry, is paid for in produce; the person performing it binding himself to deliver back five-eighths of the weight, in clean rice, receiving three-eighths with the husks for his labour. It is afterwards scalded in hot water; spread out on mats to dry in the sun; and afterwards deposited in patagis, or granaries built of teak wood. As it is of the utmost importance to preserve rice in cases of scarcity or famine, the East India Company several years ago erected a very large granary at Patna for this purpose. "It is a building of stone, in the shape of a bee hive, with two winding stair-cases on the outside, which have been ascended on horseback: by those stairs the grain is poured in at the top, there being a single door at the bottom, take it out; the walls at the bottom, though 21 feet thick, have given way. It cost 120,000 rupees; but notwithstanding the expense of erection, and the size of the building, it would not be of much use even if it were kept constantly filled, as it would not contain one day's consumption for the inhabitants of the province of Bahar, in which it stands. The district of Dacca Jellallpoor is deemed, from the immense quantity of rice which it produces, the natural granary of that grain, for all the rest of the province of Bengal.

Maize is little grown, except in the western provinces of Hindostan proper, on the poorer soils and hilly grounds. Millet is much more extensively cultivated; there are several varieties of it; though a small eared grain, it furnishes a great quantity of straw, 10 feet long, which is used as provender for the cattle. The Daob is particularly distinguished for its culture of millet. Some of the oil plants have already been mentioned; but besides mustard and flax, there are sesame, &c. some of which occupy the cold season, and others ripen soon after the rains. The crop of raggy, in the South of India, is by far the most important of any raised in the dry field, and supplies all the lower classes with their common food.

Flax is not cultivated in any part of India for the purpose of manufacturing into linen, but only for its oil; and the common hemp is grown only, that an intoxicating liquor called bang may be made from it. But sunn hemp, has lately been cultivated at Lucknow, Chittagong, Commercy, Buddhaut, Dacca, Malda, Cuttorah, &c.; the best and finest is that of Lucknow, which by experiments has been proved to be considerably superior in point of strength to Petersburg hemp; all the rest, except the Cuttorah, are also superior in this respect to Petersburgh. The Concan district of the province of Bejapoor is also noted for the excellence of its hemp.

Sugar has probably been cultivated to a considerable extent in Hindostan from time immemorial: the name of Gaur, the ancient capital of Bengal, a city highly celebrated in Hindostan antiquity, is apparently derived from gur, which both in the ancient and modern languages of India, signifies raw sugar; and that the inhabitants of India have long understood the mode of manufacturing it, seems evident, from the circumstance, that the name given to the manufactured produce, in all the European languages without exception, as well as in the Persian, Greek, and Latin, is derived from the Sanscrit term for manufactured sugar, sara. It is at present cultivated to a great extent in almost every part of India; in Hindostan Proper, it thrives best in the districts of Benares, Bahar, Rungpoor, Berboom, Burdwan, and Midnapoor; in fact there is scarcely a tract of land under the Bengal presidency, from Benares to Rungpoor, and from the borders of Assam to Cuttack, in which it is not cultivated to a considerable extent, and with great success. If we proceed farther south, we shall find it an object of great attention, and the source of much profit in the Delta of the Godavery, and in the Zemindaries of Peddapoor and Pettipoor, along the banks of the Elyseram river, in the northern Circars. In the neighbourhood of Cudapah, in the ceded districts, the sugar cane is also grown to a great extent. In short, wherever the soil is fit for this crop, and agriculture has made any advances, it is cultivated more or less in Hindostan. As it requires a soil of great fertility, it is not cultivated on the same ground a second time, till after the invention of two or three other crops; and such soils as are fit for it, let at a very high rate. One acre of sugar cane will yield on an average about ten candy of sugar, each candy weighing 500 lbs.; but the sugar cane, especially that of an inferior quality, is also made into the inspissated juice called jasyar, and of this an
Statistics.

India. 85

acre will produce more. The annual produce of 1100 acres in the Zemindaries of Peddapoor and Pettipoor is 44 cwt. per acre; consequently their whole produce will be 27,960 bushels of 1 cwt. each, which is about one-fourth part of the produce of Jamaica. The cane is planted in January, on land which has been either tilled, or prepared by a fallow, or the growth of leguminous plants: it must be watered repeatedly before the rains set in: in about ten months from the time of their planting, the canes are ready to cut. The apparatus for making the manufacturer's sugar is very simple, consisting of a mill erected in the field, or earthen or stone mortar, and wooden pestle, turned by two bullocks, boiling pots of common earthen ware, and boilers of country iron plates riveted. Six pounds of juice will yield one pound of sugar from good canes. The refuse is given to cattle, or carried away by the labourers: the sugar harvest in Hindostan, as in the West Indies, is a joyous and busy season.

Cotton is another of the agricultural productions for which India has been celebrated from the most remote times: its manufactures of cotton of extraordinary whiteness are expressly mentioned by Arrian, &c. It is cultivated very extensively, but of a better quality, as well as in greater abundance in some parts of Guzerat, Bengal, the Maharrata districts, the district of Tinamore, the vicinities of Surat, and on the coast of Coromandel, the soil and climate of which particularly suit it, than elsewhere in Hindostan. The cotton grown near Amoord in the province of Guzerat, is perhaps the finest of all; the fibre is extremely delicate, but the staple, as is the case with almost all Indian cotton, very short. The cotton grown near Nagpoor, in the province of Gujmandah, is also in great repute; considerable quantities of it are brought for the supply of the Bengal manufacture to Midnapoor, which is the great depot in this part of India for cotton. In those districts of Guzerat, which lie near the Gulf of Cambay, the cotton is of good quality, but perhaps not equal to the Ahmed cobut: it is sown here on followed spots, along with rice, the latter being reaped at the beginning of the rainy season, while the cotton stands. It is a precocious crop, as either too much or too little rain destroys it. On the banks of the Jumna its cultivation is an object of great attention; indeed the demand of the Bengal market is so extensive and regular, that the growth of this shrub must always be producible in every district, wherever the proper soil is in the reach of that market, especially as Bengal itself, with the exception of its more eastern tracts, in which a fine sort of cotton is grown for the most delicate manufactures, does not supply nearly enough of fine cotton, nor even a sufficiency of the coarser kind, though they are cultivated in every part of the province, interspersed in fields of pulse. Cotton, as it is disposed of by the cultivator, is called kopa; when divested of its seed, which is on an average full three-fourths of its weight, it is named roocoo.

As there can be little doubt that indigo is the same as the indicum of the ancients, we may reckon this plant as another of the agricultural productions of Hindostan, cultivated from time immemorial. The great demand for indigo from Hindostan, in consequence of the devastation of the plantations in the island of St. Domingo, which formerly yielded a produce nearly equal to that of all the other West India islands, has of late years very much increased the cultivation of it, especially in the British provinces under the Bengal presidency; but the culture of it by the natives has not improved, notwithstanding the increased demand, and, at first, the consequent increased price. The quality and quantity of the produce depends nearly as much on the nature of the soil, as on the mode of cultivation. In the Doobah the soil is so favourable to this plant, that what grows there in a wild state, is of superior quality to that produced by cultivation. The soil and cultivation of the Benares district are also extremely favourable to indigo; but perhaps there are few spots of equal extent, in which it is grown to a greater extent, than in the vicinity of Mowdy Ghaut in the province of Agra; from this place there was sent to Europe, from one manufacturer alone, in the year 1798, 800 mounds of 80 lb. each of manufactured indigo.

We have already adverted to the stimulus which was given to the cultivation of this plant by the state of St. Domingo: As a proof of this, we may mention, that at the sales of the East India Company, in the year 1766, only 245,011 pounds of manufactured indigo were sold: in 1807-8, the total manufacture of indigo in the Bengal presidency amounted to 8,800,000 lbs.; and in the year 1810, the total quantity of indigo, British property, which was sold at the East India Company sales, amounted to upwards of five million pounds weight. See Indigo.

The poppy, papaver somniferum, is chiefly cultivated Poppy, in Bengal, Allahabad, and Bahar. It is a very uncertain crop—the produce of an acre varying from 20 lbs. to 40 lbs. It also requires much labour in the cultivation, and in the gathering of the juice, which is afterwards evaporated into opium. Besides between 20 lbs. and 30 lbs. of the opium itself from an acre of land, the cultivator obtains about 40 lbs. of poppy seed, and frequently from the same land a crop of pot herbs, or some other early vegetables or grain. In Bahar, the cultivation of the poppy, and the manufacture of opium, are carried on so extensively, that 4000 chests of the latter may be exported annually; but it is a general complaint in Europe, that in this, as well as other provinces of Hindostan, the opium is frequently adulterated by a mixture of cow-dung, an extract from the leaves and stalk of the poppy, the gum of the mimosa, and other substances. It is said, that opium of an excellent quality is made from the poppy's gum in some parts of Northern Hindostan. In the ceded districts of Mysore, poppies are cultivated not only for the purpose of making opium, but also for the sake of their juice, from which, when ripe, an intoxicating liquor, called post, is made, that is much drunk for inebriation, both by the Mohomedans and Hindoos. The opium made from the poppies grown in Malwah is deemed much inferior to that of Bengal, and is almost always adulterated with oil and other substances. In some of the provinces in the south of India, the poppy is cultivated almost entirely on account of its seed, which is mixed with the sweet cakes that are eaten by the higher ranks of the natives.

Till lately, it was rather supposed that the tobacco Tobacco. plant was indigenous in India; but Major Hemell has shown that this notion is erroneous, as there are in existence proclamations issued by the Mogul emperors, especially one by the Emperor Jehangire, in the beginning of the 17th century, in which tobacco is mentioned as "a pernicious plant, introduced by Europeans." Besides the names by which it is known in Hindostan, even the Sanscrit names do not occur in old writings, and are evidently corruptions from the European term. Tobacco is now cultivated in almost every part of Hindostan, especially in the northern and.
INDIA.

In the western provinces of the presidency of Bengal, in Malwah, the northern circars, &c. In the southern provinces of India, it is not so commonly grown. The district round Bilsah, in the province of Malwah, belonging to Scindiah, is highly cultivated all over India for the excellent quality of its tobacco, which is in great demand, not only for home consumption, but for exportation. Such, however, is the indifference and indolence of the natives, that this high character and great demand does not appear to have stimulated them to extend the cultivation of this plant; they prefer the risk of injuring their trade, by mixing inferior tobacco with genuine British, or substituting the former entirely in the room of the latter. The tobacco grown in the Rungpoo district of Bengal, though by no means equal to that of Bilsah, is of good quality, and remarkably cheap: the southern and eastern districts of this province are principally supplied from Rungpoo.

In the vicinity of Baroath, in Guzerat, tobacco must be a productive crop, as a begah of land planted with it yielded a nett revenue to the government of 20 rupees; whereas, according to Mr. Tennant, in the northern and eastern provinces of the presidency of Bengal, “between 16 and 20 maunds of tobacco are reckoned a medium produce from three biggahs,” and the value of each maund is only a rupee.

While the crops are growing, such as require it are watered, and they are generally hoed, but by an implement which would be of little service, even if it were more industriously and skilfully used than it is by the Hindoos. In order to protect such of them as are liable to the depredations of the birds, watchmen are placed at the different corners of the fields. During the dry season, they stand upon a pillar of clay, about ten feet high, which they exchange for a seafolding of wood, with a roof of straw, as soon as the rainy season commences. These watchmen are provided with a sling; but as a consequence of the abhorrence which the Hindoos feel to the shedding of blood, they seldom or never use it, contenting themselves with bellowing, that they may terrify without hurting the birds. Maize, and some sorts of millet, when nearly ripe, require to be watched, not only during the day, but also at night, from the large kinds of bats, which would otherwise destroy the crops.

Harvest operations are performed in India in a very slovenly and imperfect manner. This arises in part from the practice already adverted to, of intermixing a great variety of crops, which ripen at different periods in the same field; and partly from the indolent habits and the ignorance of the natives. The Hindoo peasant, in Hindostan Proper, is little able, with his body almost naked, to bear the inclemency of the morning air, at the period of the spring harvest; and he is as little willing, when the weather is more favourable, to exert himself. They also want method and regularity in conducting this business; and their sickle, like all their other agricultural implements, is very rude, and very small; with this, he picks out the ripest plants. In his other hand he holds a rope, with which he ties up and carries home all that he cuts down in the course of the day. His wages consist of the tenth of the coarsest kinds of grain, and the twentieth of the finer kinds. The sheaves by which he is to be paid, are selected alternately by the reaper himself and the Ryot. When the season is far advanced, an ultimate and positive order to the Ryots for reaping the harvest is issued in the northern circars, which is called dambalah deron, literally, taking or seizing by the tail. Corn is very seldom put up in stacks; indeed, the greater part of it is thrashed in the fields, either by the cattle treading it out, or, with respect to the smaller seeds, simply by the staff of the peasant. It is winnowed by being thrown into the air, when there happens to be a little wind; and after this rude and imperfect dressing, is stored up, in Benares, the western provinces, and the south of India, in subterraneous granaries, and in Bengal and other parts, in jars of unbaked earth, or in baskets made of large twigs. If the quantity is very considerable, it is deposited in round huts, the floor of which is raised about a foot or two above the ground. Kilns of a small size, and a very simple construction, are used in the dampier climates of Hindostan, to dry the grain before it is ground. "They are large earthen pots, sunk deep in the earth, and under them is a furnace for fuel. These pots are filled with sand, which are heated almost to redness, when it is taken out, and in this state mixed with the grain. A few minutes in this mixture fits it for grinding, when it is cleared of the sand by means of a sieve." Tennant, xi. 393.

Having thus given an account of the most important parts of the arable husbandry of Hindostan, so far as it is conducted on the nungah and pungah lands, we shall briefly advert to the garden cultivation, and the principal implements by which all the three kinds are carried on, before we notice the pasture husbandry of this country.

The proper garden cultivation is most common, and carried on with the most attention, skill, and success, in the south of India. Near the town of Coimbatooar, all kinds of soil are under this cultivation, and the rent varies according to the depth below the surface at which the water stands. In some garden grounds, it is within eight cubits; in others, it is not met with nearer the surface than 18 cubits. Such gardens as are watered by machines, are called bagait, and are in great request, and pay a high rent; since from such gardens, a very large produce may be raised with more certainty than from those which are not thus watered. It is calculated, that a garden of 500 acres requires the labour of six people if it be watered from a well, but only three if it be watered from a tank. Many of the crops, which in other parts of Hindostan are grown in the fields, such as sugar cane, tobacco, &c. are cultivated in the south of India in gardens, as are also betel nut, black pepper, cardamons, plantains, &c. In the western part of the district of Soonda, where the garden cultivation is the chief and favourite object of the farmers, these are the common produce; and it is remarked, both here and in the neighbourhood of Bednore, that the garden pippins are of better quality than those which grow spontaneously, in the proportion of ten to nine. In the neighbourhood of Bangalore, in the Rajah of Mysore’s territoriy, the gardens are very fertile, possessing a soil in some places 20 feet deep. Here a gardener is a separate profession from that of a farmer, and is considered of inferior caste.

The vegetable fields, which are common in the vicinity of most large towns, nearly resemble the gardens which we have been just describing. In the south of India, they are in their greatest luxuriance and beauty in the month of November, after the rainy season has ceased. In them are cultivated, among other vegetables, the brinjal, a species of solanum, which bears a fruit as large as a pear; it is eaten by the natives either boiled or made into curry; a plant resembling the hollyoak, the seeds of which are soft and mucilaginous, and are much used in soups, &c.; various spe-
eties of cucumbers, water melons, &c. Such vegetables as are common in Europe, are seldom met with in the south of India, where the climate is too hot for them. The potato, however, both the common and sweet kind, are grown in an excellent quality near Bombay. Guzerat and Bengal also supply this vegetable in great profusion. The onion of Bombay is famous throughout the East. Orchards of mango, palmyra, and other trees, are favourite objects with the Hindoos, who, besides being sheltered by them during the hot weather, and deriving profit from their fruit, regard, with a feeling of veneration and respect, the trees planted by their ancestors.

In the gardens belonging to the Mahomedan princes, which in some parts of India were made at a very great expense, a separate piece of ground was usually allotted for each kind of plant, the whole being divided into square plots separated by walks. Thus one plot was filled with rose trees, another with pomegranates, &c. The gardens of this sort most celebrated in India were those of Bangalore and Delhi. The former belonged to Tippoo, and were made by him and his father Hyder Ali. As Bangalore is very much elevated above the sea, it enjoys a temperate climate; and in the royal gardens were seen, not only the trees already mentioned, but also the cypress, vine, and the apple, and peach: both the latter produced fruit. Strawberries were likewise raised; and oak and pine plants, brought from the Cape of Good Hope, flourished. The gardens of Shalimar near Delhi, which were made in the beginning of the 17th century by the Emperor Shajahan, are said to have cost one million Sterling, and seem to have occupied about one mile in circumference. They were surrounded by a high brick wall; but they are now entirely in ruins.

The plough used throughout all India is rude and imperfect an instrument as can well be conceived. It consists simply of two or three pieces of wood, most clumsily united, or even of a piece of crooked stick, with nothing resembling or serving the purposes of a coulter or mould-board. It is so extremely light, that a Hindoo, a man of no muscular strength, can easily carry it on his shoulder to the field. In Bengal, and generally in Hindostan Proper, it is drawn by a yoke of oxen guided by the ploughman himself. These, however, work only part of the day, as there are always two or three pair of oxen assigned to each plough. In some parts of Orissa, the women are seen holding the plough, and the female children driving the oxen. Where the same person performs both operations, he generally holds the plough with one hand, (for it has but one slit or handle), and occasionally pulls the tails of the oxen with the other. A pair of oxen may be purchased for 6 or 8 rupees, a plough for 4 or 5 rupees, and a yoke for 8 or 10. In Hindostan Proper, it is calculated that a man and two oxen can plough a bajeesh of land several times in the course of the day; and in the south of India, that 12½ acres of watered land, and 20 acres of dry land, require five ploughs. In the Zemindary near Benares, of which Mr. Tennant gives an account, 400 working cattle were kept for 300 acres under the plough. This is a larger allowance per acre than Mr. Grant, in his Analysis of the Finances of Bengali states; for, according to him, ten yoke of oxen are sufficient for the ordinary yearly threefold cultivation of 100 bajeesh of ground. Where it is necessary to plough the ground to a considerable depth, several ploughs follow one another; but even then, unless the soil is very loose and friable, they do not penetrate far, and the field remains full of dirt and rubbish. Nor is it rendered much more fit for the seed by the repeated ploughings which are given it; in Bengal to the number of three or four; in the Mysore, of seven or eight; and in the Benares, sometimes to the number of 30 or 40. Indeed, the grass roots are in general of such great length and strength, and so extremely difficult to kill, even in land that has been long arable, that a much more perfect implement than the Hindoo plough would produce very little effect. In the Mysore, it is not uncommon to see small bushes as firmly and erectly fixed in the soil, after six or eight ploughings, as they were before, and the mould not moved to the depth of three inches. The second ploughing, where only three or four are given, is generally across, and the third in a diagonal direction. The harrow is, if possible, a more imperfect implement than the plough: it is simply a bough broken from the nearest tree. The roller is described by Mr. Tennant to resemble a ladder about 18 feet in length, drawn by two bullocks, and guided by two men, who stand upon it, to increase its weight. When a plough with its yoke and oxen is hired, about 4d. a day is the sum commonly given. In most parts of Hindostan there are two kharvaars or ploughing seasons, namely, after the setting in of the rains in June, and after they cease in October. The wages of a ploughman are five seers of the grain which is in cultivation, and two rupees for each ploughing season. The wages of the other country labourers are five seers of grain, and a 25th sheaf during harvest. The hekkey, an ill-constructed and clumsy two-wheeled cart, is used by the Ryots of Bengal for some purposes on their farms, where they have not an opportunity of water carriage; but for heavy burdens to be carried to any considerable distance, oxen and bullocks are most commonly used.

The imperfect cultivation which the arable land in Mysore receives from the plough and other agricultural implements, is by no means compensated by the application of manure. The use of it is entirely unknown in most districts, except occasionally for sugar. In the Mysore it seems to be the most attended to. Every farmer in that province forms a dung-hill from the litter, &c. of his cattle, mixed with the ashes and soil of his house; the soil of the town, however, is not used. In other parts of the south of India, if the rice straw left on the field be not sufficient for the purposes of manure, small pits are dug in different parts of the field, which are filled with leaves and the tender twigs of trees, and covered with earth. These, when sufficiently rotten, are applied as manure.

The pasture land of India is in fact nothing else but Pasture land. the wastes, forests, and coarse jungle. Artificial grass would not thrive, nor even exist, during the hot weather. Even the coarse and natural grass of the country disappears in some places during the prevalence of the hot winds so completely, that the farmers are obliged to feed their cattle on the roots cut from under the ground and washed. The grass cutters, a class of people who are employed by Europeans to procure food for their horses, will bring provender from a field where there is no appearance of verdure, by means of a sharp instrument which they use. During the rainy season, indeed, the grass lands look green, and are covered with various kinds of pasture; but, for the most part, it consists of a hard grass, very similar to what is called bent in some parts of England, which is neither relished by the cattle, nor nourishing for them. There are, however, some districts in Lu-
In the north-west quarter of the province of Delhi, and partly in the northern extremity of the province of Ajmeer, there is a jungle called the Lacky Jungle, which is celebrated all over Hindostan Proper for the fertility of its pasture lands, as well as for its excellent breed of horses, which, originally good, have been much improved by Persian horses introduced at the invasion of Nadir Shah and Abdallah. This jungle, which forms a circle 49 miles in diameter, is bounded on the north by the country of Roy Kellaun, on the east by Hurianeh, on the south by Batmeer, and on the west by the Sandy Desert. The Poonneh district of Bengal is also distinguished by the extent and fertility of its pasture land. The excellence of the bullocks of Guzerat, which has already been adverted to, is, in some measure owing to the richness of its grass in those parts of the province particularly which lie near the Run, one tract of land in this district being emphatically called Waddyar, which term, in the language of Guzerat, signifies a herdman, and designated the original inhabitants of the borders of the Run. Immense herds of cattle are sent to pasture here. The tall land of India, especially the Jungale, from its evaporation and consequent coolness, is favourable to the production of those grasses which are most nourishing to cattle; and its pasture lands are accordingly extensive and rich.

The pasture lands of India, such as we have described them, are used for the grazing of the cattle that are kept for labour, subsistence, breeding, and the dairy, and for the feeding of sheep. Such cattle as are for labour are confined to the patches of grass that are interspersed with the arable land; the other cattle, as well as the sheep, are allowed to wander in the forests, &c. In either case, it is necessary that they should be watched and prevented, either from injuring the arable land, or going astray. For, in many parts of India, the only fences consist of a low bank. In some parts of Delhi and the adjoining provinces, indeed, the strong jungle grass is platted into a kind of basket work, which is carried along the sides of the field to protect the grain from the cattle. In Guzerat, the fields are divided and protected by dry stone walls; and in the south of India, fences of the milk bush are not uncommon. Besides the shepherds who have fixed residences, there are found, in many districts of Hindostan Proper, shepherds who come from the native districts of the Indies in search of employment. They are scattered all over the Punjab and the high grounds to the east of the Indus. The herdsmen is in every case a person attached to the farm on which he is employed.

Milk, ghee, and cheese, are the produce of the cows and female buffaloes. In various parts of Guzerat, Cutch, and the Decan, there is a particular tribe, whose chief employment is selling milk and day-labouring. In the provinces of Hindostan Proper, it is calculated that the produce of each cow, annually, is nearly 1500 mounds of milk; and that one maund will produce 2½ seer of ghee or clarified butter. Ghee is made of butter which is kept for two or three days; in this time it becomes rancid, after which it is melted in an earthen pot, and boiled till all the water has evaporated; it is then poured into pots, or leathern jars, and kept for use. Some cheese is made in Guzerat, and other provinces in Hindostan Proper, but it is of very inferior quality. The wool of the sheep is of little value, except in those districts where the climate requires clothing warmer than that which cotton will supply; in those districts the sheep are generally shorn twice a year, once in the cold, and once in the rainy season; it is calculated that 12 sheep will furnish wool sufficient to make a blanket six cubits long and three wide.

In discussing the nature of the landed tenure in India, we incidentally noticed some particulars relative to the condition and circumstances of the Ryot or husbandman; it will be proper, however, before we close this chapter, to attend to this subject more directly, and rather more fully.

In Hindostan Proper, the Ryots hold their lands either directly from the zemindars, or from the talookdans; the latter are of two sorts; some of them pay the rent, and account for the collections they make from the Ryots to the zemindars; others to government: the latter are called independent talookdans, and are in fact only petty zemindars. The poorest Ryots are, by the custom of the country, considered as a sort of proprietors, entitled to a perpetual lease; they are attached in the strongest manner to the soil, and never migrate but in cases of absolute necessity. Waste or uncultivated land, which is fit for rice, can be brought into cultivation in one season, and the poorest Ryot can undertake it; he can with ease cultivate 16 bighas of rice, and supposing the half to go for rent, the remainder will afford food for four or five persons. Such was the state of the poorer Ryots before the British acquired a permanent and extensive footing in Hindostan Proper, under such zemindars as were just and equitable landlords, and regulated their conduct toward their tenants by the customs of the country; but the condition of those who rented their land under the generality of zemindars was quite the reverse: agreements, indeed, did pass between the landlords and their tenants at the beginning of the year, but they were commonly broken by the zemindar.

The condition and circumstances of those Ryots, who occupy more land than they can cultivate by themselves and families, and who, of course, are obliged to hire servants, do not appear so favourable. From the produce of their crops they are obliged to give, not only the necessary servants of the farm, high grain wages, as well as money, but also the poet, Brahmin, blacksmith, &c. so that, after deducting from the produce of his land, that part of it which they require, and that part which is paid to the zemindar for rent, the share of the ryot himself will be but small. It should be observed, however, that his whole stock is small; in the district about Allahabad, it does not amount to eight rupees, exclusive of the value of his cattle. The cultivation of the province of Bengal, according to Mr. Grant, does not require a greater agricultural stock than a cow and a half of rupees.

The preceding observations apply to the cultivators in the south in Hindostan Proper; those in the south of India, especially in those provinces which were least affected by the Mahomedan conquest, are in a better condition. The Ryots here hold directly under the government, or rather pay rent as revenue to government. Districts are divided into villages, and each village is under the management of a Potal, or head farmer, in what are called the sixteenth villages, from the land and rent being divided into sixteenth shares. All the Ryots assemble to fix their respective rents, a little before the season when cultivation commences; the amount of the agricultural stock possessed by each individual, the quantity of land, its probable produce, are ascertained, and the rent is then fixed; and such a per-
tion of land assigned to each person as he has the means of properly cultivating. In other parts the custom is different, and the rent is fixed by the agents of government; these set out on their circuit in September or October, when the early crops begin to be reaped, and the late ones to be sown: if the cultivation is the same as last year, and no failure occur among the Ryots, there is no alteration in the soil; if waste land has been brought in, the full rent is not exacted for three or four years, according to its previous state: if it appears that some of the Ryots, from the failure of their crops, cannot pay their rent, the loss, or a part of it, is sometimes assessed upon the others; but this is seldom done. When the land is in cultivation, and its rent has been ascertained, the collector gives every ryot a pattah, with his signature, in which every field he holds, and its rent for the year, are inserted. In most villages the greatest part of the ryots hold the same fields several years. During the intervals of the rents of the collectors, the agricultural concerns of the village are regulated and overlooked by a complete establishment of hereditary revenue servants. A district pays a rent or revenue of 50,000 pagodas, usually contains about 100 villages, some of which pay not more than 100, and others as much as 5000 pagodas, annual rent. The general direction of the cultivation, and the collecting of the rent, is the duty of the Potail, or head farmer; the accounts are kept by the Curum. As soon as the season for ploughing begins, the Potail ascertains what land each ryot can cultivate; and if any are desirous to relinquish part of their farms, he gives it to another. In the early part of the season, the Tehsildar goes round the district; his duty is to regulate cultivation in those villages which are mismanaged, through the neglect or incapacity of the Potail, and to make advances to the poorer Ryots for the purchase of seed, ploughs, or cattle: he goes round again when the crops are ripening, to see their condition, and to ascertain whether the quantity of land actually cultivated, is more or less than that which the Ryots had engaged to take. None of these, however, have power to fix the rent; this is done exclusively by the collector; but the Potail assures the Ryots that the rents will remain the same, unless some alteration should appear to be indispensably necessary; they are satisfied with this assurance, receive betel from him as a confirmation of it, and yoke their ploughs.

Among the Maharratas, when a Ryot once rents a piece of land, he can never leave it, nor even relinquish a part of it. If he were to be deprived of the assistance of his children, or such relations as cultivated it with him, he must still continue to hold it, and pay his rent as usual. Even the widows are obliged, after the death of their husbands, to engage for the usual quantity of land.

The Brahmins have been already noticed as the proprietors of villages in the south of India. In the Carnatic they also rent a considerable quantity of land; but they will not hold the plough, nor perform any other part of the labour necessary for its cultivation. The inferior castes, particularly the Sudras, are obliged to cultivate them, and are in fact their slaves. There are, however, some Sudras who rent farms on their own account, which they cultivate, either by their own labour, or by slaves. The Mahonnean farmers in this part of Hindostan are not numerous; their agricultural labour, in general, is performed by slaves. The Haiga Brahmins, who live in the province of North Canara, above the Ghaunts, differ from the Brahmins in most other parts of India; for they are very industrious, and perform all agricultural operations with their own hands.

The agricultural labourers in Hindostan are either such as work for hire, or slaves. The condition of the former, as has been already remarked, is by no means unfavourable. His money wages, indeed, are low. In Bengal, where a ploughman is hired by the month, he receives one rupee, in some parts only half a rupee for that period; but, in addition to this, he has an allowance of grain, and at his leisure hours cultivates some land, which he rents from his master at a payment in kind. A herdsman receives, in food, money, and clothing, about one rupee and a half per month. The wages of the other labourers are chiefly in kind. In the neighbourhood of Seringapatam, the hire of farm labourers is six rupees per month; but in the country, at a distance from any large town, it is much less. On the Malabar coast, agricultural labour varies from two rupees to six rupees a month. Such a comparatively high rate, however, it should be observed, includes the value of all that the labourer receives in kind. The average price of agricultural labour in the ceded districts is about two rupees a month; and this, indeed, seems to be about the average of Hindostan, independent of allowances in kind. If, therefore, the very low price of all commodities in Hindostan be considered, and it be further taken into account, that the agricultural labour requires very few of them, we shall be disposed to regard their situation as by no means uncomfortable.

The slaves who labour the farms in the south of India, are the absolute property of their lords; but they slaves, are not like the slaves in Russia, &c. attached to the soil: they may be sold or transferred to any person their master may think fit. Children may be separated from their parents, but a husband and wife cannot be sold separately. In the district of Palghaut, in the province of Malabar, where the greater part of the labour of the field is performed by slaves of different castes, a young man and his wife will sell from £6. 4s. to £7. 8s.; if there be children, the value will be increased according to their number and ages. They live in temporary huts, formed of the bamboo and other wood, something like large baskets, which they erect for themselves. The personal labour of the wife is always at the disposal of the master of the husband; the master of the girl having no authority over her, so long as she lives with the slave of another man.

The women and children of the free labourers, as well as of the slaves engaged in agriculture, are principally employed in protecting the seed and crop from the birds, in those districts where this is not performed by men.

CHAP. V.

Manufactures.—Cotton—Silk—Woollen—Leather, &c.—Saltpetre, &c.—Trade and Commerce.

Or all the various manufactures carried on in India, Manufacture of cotton claims our first and most extended notice, on account of its antiquity, of its being the staple and most common manufacture of the country, and of the variety of the fabrics which it produces. The perfection to which the natives are known, from the
most remote times, to have carried the cotton manufacture, must be mainly attributed to the circumstance, that every distinct kind of cloth is the produce of a particular district, in which the mode of manufacturing it has been transmitted for centuries from father to son.

The province of Bengal, and the eastern side of the Peninsula, are the principal seats of the cotton manufacture. The vicinity of Simoga, a town in the Mysore Rajah's dominions, 122 miles to the north-west of Seringapatam, is the limit of the manufacture of cotton to the westward, in this part of India; and, with the exception of a particular kind of chintz made at Poona, and painted with gold and silver, there are as fine cotton cloths made on the western side of the Peninsula. On the eastern side, the Madras investment of cotton piece goods for the East India Company is provided from Cape Comorin and Ganjam, in the northern Circars, a distance of about 1,500 miles. The principal part of this investment is provided in the northern Circars. In Bengal, this manufacture, in almost all its branches, flourishes very extensively. It also extends into the provinces of Oude, Allahabad, particularly the Benares district, Bahar, and Orissa.

There are such varieties in the fineness and other qualities of the cotton goods, especially of the calicoes manufactured in India, that it would carry us beyond our proper limits to particularise each kind; and, indeed, most of them are scarcely known in Europe, or merely known by their Indian appellations. Coarse cotton cloth is manufactured in different parts of the province of Agra. In the centre of the Doab, there is a kind very coarse and common, which is dyed red with cheap materials. The coarsest sort of blue-handkerchiefs are manufactured near Calcutta. The greater part of the return cargo carried annually from the northern parts of Bengal to Bootan, consists of coarse cotton goods, which are the staple commodity of Rung-poor. The cotton goods made in the more southern parts of India, in general are not coarse, though there are goods of this description manufactured in the northern Circars, both to the north and south of the Godavery; these are either plain or coloured with chay root, which grows in most perfection on the pure sands annually overflowed by the Krishna. There is also a manufacture of coarse cotton cloths at Arocot.

Dacca, in the eastern quarter of the province of Bengal, has long been celebrated for the manufacture of the finest muslins. In this district, there is grown a kind of cotton, called Banga, which, though not of a very superior quality, is necessary to form the stripes of such muslins; and this circumstance may have contributed to the perfection of the fabric at Dacca. The manufacture, however, is in a declining state, owing to several causes. Before the fall of the imperial government, those delicate and beautiful fabrics were held in such estimation, not only at the court of the emperor, but amongst all the higher orders of the nobility in India, as to render it a matter of difficulty to supply the demand for them. The almost entire cessation of this demand, must have greatly contributed to injure this manufacture. But, besides this cause, another must be sought for in the perfection to which the muslin manufacture of Britain has recently been brought. In consequence of the falling off in the demand, many of the families who possessed the hereditary knowledge of manufacturing these very fine muslins have given up the business. So minute is the labour bestowed upon them, that a weaver will require five or six months to execute a piece. Besides those very fine muslins, plain muslins of an inferior quality, as well as flowered, striped, and checkered muslins, are manufactured in the district of Dacca, and in the northern parts of Benares. The manufacture of muslins in pieces, chiefly for turbans, is carried on to a great extent in the Cuttack district of Orissa. Dimities of various kinds and patterns, and cloths resembling diaper and damask linen, are made at Dacca, Patna, Taunda, and other places. Chinizes are manufactured principally in the district of Benares, and in the country around Patna and Calcutta; in Hindostan Proper, and at Masulipatam in the south of India. This last place has long been famous for this kind of manufacture, which is in great demand at Bombay and in Persia. Masulipatam and Madras are also celebrated for their palampores, the groundwork of which is formed of the plain long cloth, chiefly wrought in the island of Nagur and its vicinity.

The first process necessary to prepare the cotton for process, being manufactured, is to separate the wool from the seed; the cotton encircles a black seed, and advances perhaps half an inch upon it. To separate them, the natives of Cuddah. Hindostan make use of three cylinders that go different ways. As these move closely together, when the cotton is introduced between them, the wool is drawn out, and the seed is left behind. This simple machine is found in every house, and is worked either by the spinner, or even by children. The second process is performed by a sort of bow, something like what the haters use in Europe to prepare the wool for making hats. One end of this is fastened to the ceiling; the workman holds it by the middle, while, at the same time, with a piece of wood that has a pad at the end of it, he stretches the cat-gut string of the bow. This, by its elasticity, beats the cotton, separates the dust and seeds that may remain after the first process, swells it out, and, in short, answers the purpose of carding, and puts it in a state to be spun. It is remarkable, that this process is performed, in a country where there are so many species of Hindoes, by Mahommedians, called Choulos, of the sect of Ali. They are of Arabian descent. There are one or two such persons in every village of the Northern Circars, who performs two operations, that of cleaning cotton, and of spinning the warp.

The spinning of the cotton thread which is to serve as a woof for the weft, is the occupation of the females of almost all the castes, except the Brahmins; but particularly of the cultivating caste, and of such families as are in decayed circumstances, and, having few means of employment themselves, from the secluded nature of their mode of life, derive from this occupation the supply of their few and humble wants. The spinners purchase the cotton which they may require weekly, at the market; and this is done in so simple a style, and with so much attention to economy, that the weaver, perfectly well acquainted with the price of the raw material, seldom affords to the spinner more than he thinks a just return for the labour of the week: and that matter is so well understood among the weavers generally, that no weaver, for the sake of getting a larger quantity of thread, will outbid his neighbours in the purchase of it.---Evidence before the Select Committee as to the affairs of the East India Company.

The weavers live entirely in villages; and on the Weaving coast of Coromandel, and in the province of Bengal, which, as we have seen, are the chief seats of the cotton manufacture, there is scarcely a village, at a short distance from the high road, or a principal town, in which every man, woman, and child, is not employed in making a piece of cloth. As the thread is laid the
whole length of the piece, the weaver is under the necessity of working in the open air. In the morning he fixes his loom under a tree before his house, and in the evening he takes it home. It consists merely of two rollers, placed on four pieces of wood, which are fixed in the ground, and two sticks which traverse the warp. One of these is supported by two strings tied to the tree under which the loom is placed, and the other by two strings fastened to the foot of the weaver. By means of these he can easily remove the threads of the warp when he is throwing the woof.

The weavers are of a respectable caste, and many of them are cultivators of land. The demand for their work has greatly increased since the British gained possession of Hindostan, in consequence of the large investments of the East India Company. As soon as an order for an investment from the Court of Directors arrives in India, the Board of Trade there makes a calculation of the sums required for the provisioning of the goods allotted to each factory. Under the Madras presidency there are eleven factories, most of which provide distinct kinds of goods. It is calculated that all these factories are capable of producing goods to the amount of 244000 of pagodas, or one million Sterling. The actual demand varies from 200000 to 240000. If the weavers do not live near a factory, native agents are employed to engage them, convey the money to be advanced to them, bring the goods in, and save the Company from all risk. Where the weavers live near a factory, the contract is made with them directly; and it is not uncommon for all the weavers inhabiting a village, perhaps to the number of 100, to become security, jointly, for the due performance of the contract, which is entered into by each. An advance in goods or money is always made to the weaver, and this he retains in his hand till three-fourths of his contract are completed; the original advance, if in cotton, is then worked up. There are four kinds of goods, for each of which there is a standard price; and if, on inspection, any are found, from deficiencies in length or breadth, or inferiority of quality, not equal to the first class, they are reduced to the second, third, or fourth, with a difference of 25 per cent. between each number. It frequently happens, that a weaver, after getting his advance in money, resorts to the weekly markets all over the country to procure materials for his web, and after having procured what will suffice for one piece of cloth, he spends the rest of the money in a cock-fight, or any other species of gambling that is going on in the market. The practice of making advances to the weavers has existed ever since the establishment of the East India Company. If the weaver does not deliver in his goods at the periods specified in the contract, a per cent is placed in his house, who receives subsistence-money, at the rate of one anna per day from him; it was a prevalent practice under the native governments to place per cents. The monthly profits of the weaver vary from three to five rupees, according to the price of thread, the quality of the cloth manufactured, and his own industry, experience, and skill.

The cloths are generally bleached at the station where they are manufactured. The waters of the Nerbuddah are said to possess a peculiar property of bleaching cloths to a pure white. Most of the pieces are twice bleached. Others are not bleached at all, but are dipped in cocoa-nut oil, in order that they may be the longer preserved. They are also sometimes washed, or rather rinsed, in rice water, with a view to give them smoothness, and the appearance and feel of closeness and strength.

The coloured cotton stuffs are prepared in different ways, all of which are as simple and rude as the previous processes. The most common method, formerly, was for the dyer and his family to wear next their skin, for a week or more, the cotton cloths as they came from the bleachfield. The next steps were to macerate them in water, impregnated with goats' dung; to wash them frequently in pure water; and to expose them to the noon-day sun. They were next soaked in buffalo's milk, curdled by some astringent plant, and were again exposed to the sun. After these preparations, and having been rendered smooth by pressure and friction, they were ready for the mordants. These consisted chiefly of a liquor, made by dissolving iron in sour palm wine, and of rice-water. Such parts of the cotton cloth as were intended to be figured, or spotted black, were washed with these mordants. The next mordant was slum-water, applied to the places which were to be red, generally by children. The pieces were then exposed to the hottest sunshine, in order that the parts in which these mordants had been used might be rendered thoroughly dry. Before the dying process was performed, they were freed from all the impurities that the buffalo's milk, &c. might have left in them, by being soaked in pits of water.

The following is an account of the modern practice. Modern as it was communicated to Mr. Parkes by a gentleman, who had spent some time in India. "The finest chintz counterpanes, which the natives call palampores, are manufactured at Madras. These are woven in one piece, from two to four yards square; and are printed, or rather painted, with various designs, and in various colours. Their method is to draw their pattern first on sheets of paper sewn together, of the size of the intended palampore, and then to prick out the same in the paper with a sharp instrument. This done, the paper pattern is smoothly fixed upon the cloth, which is previously dampened, and a small muslin bag, containing some kind of black powder, is rubbed over the whole, in order to force a part of the powder through the pin holes, and completely mark out the pattern. "The pattern being thus sketched upon the cloth, the paper is removed; and when the outline of the various figures is drawn with a pencil, the piece is considered to be ready for receiving the colours. "One colour is then laid on with a brush, made with a tough root of a particular kind of tree, or with the husk of the cocoa-nut; and when this dries, the piece of cotton is given to a woman to wear, or to use in the family, till it be very much dirtied, in order that it might necessarily undergo a thorough washing, which is thought requisite to prove the goodness and permanency of the colour. Another colour is then laid on in the same manner, and the piece is again submitted to the same trial of wearing and washing. This is repeated for every colour that is employed; and when any one of these colours is found to be deteriorated by this treatment, it is printed anew, and so are all the rest, till the workman is satisfied that all the colours are actually permanent. "This tedious process is adopted, however, only when the manufacturer means to warrant the article; but in all cases, even in those pieces which will not bear washing, the colours are laid on by a brush as before mentioned."—Parkes' Chemical Essays, vol. ii. p. 94—98.
In some cases, children are employed, after the outline is drawn, in putting on the principal colours; but the shades and more delicate parts are executed by the most skilful workmen, the cloth being extended on a small narrow table. The brushes and pencils employed, and mentioned in the extract from Mr. Parker, are made either of the fibres of the rhind of the cocoa-nut, hemp, or flax, to give it the appearance of horse hair; (this is very elastic, and therefore answers the purpose very well,) or they are made, in those cases which require a firmer and finer point, of a piece of bamboo split. A little cotton-wool is fixed about an inch above the extremity to retain the colour, and this the workman presses to make the colour descend to the pencil.

We are not acquainted with the nature of all the dyes which the Indians employ; but some of them are well known. The indigo is the principal. The Romans were acquainted with the deep blue colour of this dye, and gave it the name of Indicum. By them it was held in high estimation. It is mentioned, under the name of Indicus nigrum, among the articles of importation from India, in the Periplus of the Erythraean Sea. The red and the blue are the colours of most conspicuous lustre and beauty in the cotton and silk stuffs receive from India at present; and this seems to have been the case in the time of the ancients, for Indian dyers was the ancient name of those who dyed either of these colours with great perfection and delicacy. The source of the blue colour has been just mentioned. The red is dyed principally by means of gum lac. This also was known to the ancients. Ctesias appears to have learnt pretty accurately the nature of the insect which produces it; and he expresses his admiration at the beauty of the colour which it produces. The insect which supplies the gum lac is found on a tree called bhaar in Assam, a country to the north-east of Bengal; on a tree called jala, growing on many of the hills in the Rajah of Mysore's territories; and in other parts of India. There are also some flowers, roots, and fruits, which are employed to dye red; but the red of the gum lac is the most delicate and beautiful. The semecarpus anacardium, or marking nut, which is a native of all the mountainous regions of India, is used for giving a durable black stain to the cotton cloth; and a yellow dye is supplied by the curcuma, or Indian saffron.

Of the capital employed in the cotton manufacture of India generally, it is impossible to form even the slightest conjecture. The materials for the following estimate of the capital employed in this manufacture in Bengal, are supplied by Mr. Grant, in his Analysis of the Finances of that Province, printed in the Fifth Report on the Affairs of the East India Company. He supposes, that the produce of cotton in Bengal is equal to four lacks of maunds; which, after losing three-fourths of its gross weight, by the operations of cleaning and dressing, will sell for about twelve lacks of rupees. There is, besides, imported into Bengal, for the use of the cotton manufacturers, cotton from Surat and Mirzapore, in the district of Benares, of the value of six lacks of rupees; so that the total value of the rude materials used in the cotton manufactures of Bengal may be estimated at eighteen lacks of rupees. The price of fine thread is enhanced to sixteen times the value of the raw material; yet it is a remarkable fact, that the labour which thus enhances the value of it, scarcely yields a subsistence of nine annas, or about 18 pence per month, being no more than three farthings a day to each spinner,—perhaps 18,000 in all. They could not labour so cheaply, were it not that they are principally the wives and daughters of the husbandmen and manufacturers, who could not otherwise be so usefully employed, at least during the hot and rainy seasons.

The number of weavers, masters and journeymen, Mr. Grant estimates at 300,000, who are generally employed in making three million of pieces of cloth annually, the prime cost of which is about 2 kröre and 65 lacks of rupees; yet, as the amount of thread is not above half the price of the finished manufacture, and as the capital laid out in the purchase of such materials seldom or ever can equal the consumption of two months labour, so the whole productive stock at any time required, or actually in use, for completing all those beautiful fabrics, so much the object of our admiration, after allowing a loom, of six rupees, to be renewed once in 20 years for every workman, will not exceed 25 lacks of rupees.

The manufacture of silk next claims our notice. Though the Romans procured their silk from China, and were obliged to depend upon the Persians for a supply of it, there is little doubt that, at this period, it was manufactured in Hindostan. In the Sanscrit there are names for the silk worm and manufactured silk; and what is more decisive on this point, there are, and appears to have been from the remotest times, two castes of Hindoos, whose respective employments were the feeding of silk worms and the spinning of silk. In the year 1762, when the power of the East India Company was pretty firmly established in Hindostan Proper, they sent over some natives of Italy to introduce the Italian mode of spinning. The first attempt to establish a silk manufacture was a little below Calcutta; this, however, did not succeed. In the year 1773, buildings for that purpose were erected at Jungsypoor, in the Raujeshy district of Bengal; and in the year 1803, about 3000 people were employed here. This is the greatest silk station of the East India Company. The others are at Cossimbazar, Maudlah, Baulaeh, Commerically, Radnagoor, and Rungpoor. It is calculated, that the district of Raujeshy, in which these places are situated, supplies four-fifths of all the silk, raw or manufactured, used in, or exported from Hindostan. The raising of silk worms is principally confined to a part of the district of Burdwan, and to the vicinity of the Bhagirathi and Great Ganges, from the fork of these rivers, for about 100 miles down their streams. The introduction of the silk worm has not yet succeeded in the warmer districts of Hindostan, but it is probable that the country above the Ghauts, where the climate is temperate, will be found suitable.

The mulberry tree used for feeding the worms is the Mulberries Oriental; the dryness of the soil, it is supposed, is prejudicial to the China mulberry. The expense of planting this tree on a biggha of land is about 14 rupees; and the annual expenses afterwards, 9 rupees. Twenty rupees are generally given by the feeders, for the leaves of a biggha. From one biggha, two mounds of cocoons may be produced; and two seer of reeled silk is the produce of one mound. Four crops of mulberry leaves are obtained from the same field in the course of the year.

Wild silk worms are common in the forests of Silhit, Wild silk Assam, and the Decan; from them a kind of coarse silk, called tisser, is procured, which is very far inferior in colour and lustre to the other silk. In Silhit, it is manufactured into a kind of goods called muga-dooties; but it is principally manufactured, mixed with wool or cotton, into an article in considerable re-
quest in India, and by no means destitute of beauty or
elegance. Much of it is also exported, wrought or un-
worked, to the western parts of India.

The best cocoons of the domesticated silk worms are
sold by the natives to the Company; from the rest they
wind off the silk. But previous to this, the cocoons
are immersed in a mixture of water and the excretions
of the worms, till a fermentation commences, when
they are boiled in an earthen vessel. "The women
wind off the silk from the pod of the worm. A single
pod of raw silk is divided into twenty different degrees
of fineness; and so exquisite is the feeling of these
women, that whilst the thread is running through their
fingers so swiftly that their eye can be of no assistance,
they will break it off exactly as the assortments change,
at once from the first to the twentieth, from the nineteenth
to the second." Corne's Fragments, 412. A hand reel is employed for this purpose, which resembles
in its simplicity and cheapness, all the other implements
used by the natives.

The most extensive and flourishing manufacture of
woollen silks is at Mawbalabad and its neighbourhood; there are also made various kinds of taffetas, plain and
plaid, and other sorts of silk goods, both for home
consumption and exportation. In the district of Bena-
res, brocades, and ornamented gauzes are manufactured: in the western and southern parts of Bengal, plain gauzes, principally for home consump-
tion, and mixed goods of silk and cotton at Moolah,
Baglipoor, and in some parts of the district of Burd-
wan. Silk stockings are knitted with wire in the neigh-
bourhood of Coimbatore; they are esteemed the best
in Bengal: here are also made satins, silks, cloths, &c.
Though the silk worm has not yet been introduced in-
to the Carnatic, and probably would not thrive there,
yet in this province, the silk weavers make goods of a
very strong fabric. Mr. Grant calculates that the
trading stock constantly employed in the whole of this
species of manufacture, in Bengal and Benares, the
chief seats of it, may reasonably be estimated at 10
lacks of rupees, while the prime cost of the raw silk
produced in the country, chiefly for foreign exporta-
tion, he estimates at 50 lacks; the largest portion of
which is advanced by the great foreign exporter; the
sum paid to the workmen he calculates at 1 lack.

The other manufactures of Hindostan are not of
great extent or value, and may therefore be noticed in
a more cursory manner. In all the colder parts of
Hindostan, particularly in the elevated districts of the
Mysore, the natives wear woollen clothes, called cere-
liyes; they are worn as they come from the loom, and
are of different lengths; some being six or seven feet
long by four or five broad; these are of coarser quali-
ty; such as are of a finer texture, are about ten feet
long, and seven broad. These resemble Eng-
lish camlets. Neither of the kinds are dyed, but are of
the natural colour of the wool, which, in the fine
ones, is almost always a good black; the price of the
coarser kind is from eighteen-pence to two shillings,
and the finer from twelve to fifteen shillings. The
Chittelledroog district of Mysore is celebrated for the
manufacture of excellent camlets, that is of such as
keep the natives warm, and protect them from the
rain. Flannels well wove, but fullif in a very imper-
fect manner, are manufactured at Patna. Carpeting,
of a very durable fabric, is made in the Churrar district
of Allahabad; and Ellor, the capital of one of the
Northern Circars of the same name, is famous for car-
pets of a rich and beautiful texture. The best coil
cables are made at Anjengo and Cochin, of the fibres
of the lacinade comnut. Canvas is manufactured
from cotton and from the sun hemp; the former in the
neighbourhood of Chittagong, Patna, and some other
places, and the latter at Calcutta. In this city
there are upwards of 70 looms at work, which can
make 150 bolts monthly at least; the workmen are
paid at the rate of four rupees for every bolt; one
man, if commonly industrious, is capable of weaving
one bolt in ten days, and at that rate might earn 12
rupees a month; but he seldom finishes his bolt un-
der 15 days; some take 17 days. As soon as a native
workman is paid his four rupees, he quits his loom,
and seldom returns till his money is spent. About
200 people are employed in this manufactury. The
canvas is of the same length, breadth, and weight as
the English canvas; it has a drop upon it, which is
removed by bleaching and washing. Pack thread is
wove into sackcloth in many places, particularly in the
northern parts of Bengal, where it is used as clothing
by the mountaineers. A coarse, but very strong sack-
cloth, is also made at Bangalore, in the Mysore, from
the Indian hemp.

Saddles, harness, military accoutrements, and other Saddles,
articles of leather are manufactured by the natives in
Bengal. Leather pantaloons for the artillery, and gloves
are made at Madras, and shoes all over India. The
Bombay shoes are reckoned the best. Hyderabad, the
capital of Sinde, is noted for its artificers who embroi-
der on leather. Great numbers of brazen water-pots
are manufactured at Bareilly, in the province of Delhi.
Articles of cutlery, and even brass instruments, are
made in some parts in tolerable perfection. The swords
made in the Decan, and in the north part of India, are
equal in temper, &c. to the best swords made in any
other part of the world. The armourers of Hyderabad,
in Sinde, are celebrated for the excellence of their work-
manship; and at Poona, in the territories of the
Nizam, there is a large manufactory of matchlocks,
spears, and other weapons. At Muttedon, in the My-
sore Rajah's dominions, the glass is manufactured which
is used for making the rings which are worn by the
Hindoo women round their wrists. The quality of
this glass is not good, the materials of which it is form-
med not being well sorted, mixed in due proportion,
nor fused sufficiently,—in consequence of which it is
coarse and opaque. It is made of five colours, black,
green, red, blue, and yellow. The black is in the most
request, and bears the highest price. The natives ob-
tain the soda that they use in the manufacture in the
fields, where it forms during the hot season. The
same fields supply them with sand. The ring makers
on the western side of India purchase the greater part
of this glass. Vizagapatam is celebrated for its beau-
tiful cabinet work, which is painted and inlaid with
ivory and black wood with great elegance and art.

The manufactures of opium and indigo have already
been mentioned. About twenty years ago, the cochi-
neal insect was introduced into India; and cochineal,
though of an inferior kind, is now produced in different
parts of India. The insect is found to thrive best on
the indigenous opuntia, which is abundant in Bengal,
and in most parts of India. Near Bailora, in the Mys-
ore Rajah's territories, the husbandmen keep the in-
spect on the opuntias, which serve as a fence to their
gardens, and make from it annually about 1500 pounds
of cochineal. Tar is extracted from teakwood in most Tar.
of the places where ships are built of it. Rose-wa-
ter is distilled in many parts. Gazapoor, in the Be-

Statistics.
The hammer, that is working, is kept superior.

Salt petre is manufactured to a great extent in the provinces of Bengal and Bahar, particularly in the latter. The export of it is principally confined to the Company's investment, the greater part of which is made in the districts of Hojipoor and Sanur, in Bahar. The climate and soil are extremely favourable to its spontaneous production. It is sent to Europe in an impure state, but chrystallized, put up in bags, each bag containing two bazar maunds, or about 1014 lbs. As the Company are obliged to supply the British Government with a certain quantity of it, each Bengal ship of 800 tons, in time of war, generally brings home about 5000 bags. Salt is made from sea water along nearly the whole of the eastern coast, as far as the mouth of the Ganges, in great abundance. Tumlock and Hiljelle, which lie to the south-west of Calcutta, near the Hooghly, are the principal places where salt is manufactured for the Bengal presidency. The land at these places is regularly overflowed by the tides; and in order to retain the saline particles, mounds of earth are formed, from which the salt is extracted by filtration and boiling: each mound will yield, on an average, 18,640 lbs. of salt, and requires the labour of seven men. The working months are from November to June, during the dry season. On the West coast of India, salt is made in large quantities, on the coast of the island of Sylhet. The process is similar to that which is followed in Europe; but when salt of a superior quality is wished for, it is obtained "by fixing a jagged piece of stick in the water, when first let into the reservoirs, to which, as the water evaporates, saline particles adhere, to the weight of three or four ounces." Salt made from sea water is in high repute among the natives of India, principally from religious considerations, especially that made from the waters of the Ganges: but European tables at Bombay, and other places on the western coast, are supplied with a remarkably fine salt from Arabia, "in pieces not unlike a cheese in shape, and sparkling like a sugar loaf."

The mechanism of the Hindoos is very rude and imperfect, and probably has been stationary for at least 2000 years. The rice mill consists of two round flat stones: in the lower one there is a hollow, into which the middle of the upper one is inserted: it is turned round by means of a wooden peg, and the flour comes out through a groove in the under stone; in fact, it resembles the grun of Scotland. Two Indians with their hand corn mill can grind only 60 lbs. of flour in a day. On several of the streams, however, in Hindostan Proper, particularly on the Ravey, there are water-mills for grinding corn. The mill that is used to extract the oil from the cocoa-nut is very simple in its construction, and, at the same time, answers its purpose extremely well. It is thus described by Sonnerat:

"The pieces of this machine are, first, the trunk of a large tree sunk in the earth, and strongly fixed, the top in the form of a vase; secondly, a mortar placed in the middle of the trunk, and which, not being very large, goes widening to the bottom; thirdly, a pestle placed in the mortar; fourthly, a cross pole, adapted to the top of the pestle, and which turns it; this cross pole is composed of equal pieces, tied together with ropes, which, being flexible, are not subject to break; fifthly, a large bar of wood, flat, placed horizontally at the bottom of the machine, and to which the cross pole is fixed. This bar, widening and increasing towards the extremity, which is fitted to the trunk of the tree, turns on a slope made at the bottom of the trunk, and regulates the machine. Two bullocks, tied to this bar, turn it, and the people along with it. At the top of the trunk, is a ledge to prevent the oil from running out. A man stands on the horizontal bar, and turns along with it,—puts back the grains that are falling out,—collects the oil as soon as it rises to the top, and puts it into vases." Sonnerat's Voyage to the East Indies, vol. ii. p. 133.

The same author thus describes the arts of the carpenter, sawyer, blacksmith, goldsmith, and shoemaker, as they are carried on in India:

"The Indian carpenter knows no other tools than the plane, chisel, the wimble, a hammer, and a kind of hatchet. The earth serves him for a shop-board, and his foot for a hold-fast; but they are a month in performing what our workmen will do in three days. It is to no purpose shewing them the most expeditious and easy way of sawing wood; they had rather keep to the imperfect manner they received from their fathers, than adopt a new one more commodious."

"The Sawyer places his wood between two joists fixed in the ground; and, sitting carefully on a little bench, employs three days, with one saw, to make a plank, which would take our people an hour's work.

"The Blacksmith always carries his tools with him, his forge, and his little furnace; working wherever he is employed. He sets up his forge before the house of the person who calls him, and, with the dirt of the place, makes a little wall, before which he places his hearth. Behind the wall are two leather bellows, which the apprentice keeps going, by alternately pressing the top. In this manner the fire is kept up. A stone serves for an anvil, and his whole apparatus consists of a pair of pincers, a hammer, a mallet, and a file.

"The productions of the goldsmith announce, in every shape, the want of tools. Like the Chinese, they have not as yet arrived at the art of polishing gold or silver, or to work the gold in different colours. Yet we have their filigree work in esteem; that is, indeed, only a work of patience. The Indian goldsmith carries his workshop with him wherever he is sent for. His furnace is an earthen pot, an iron pipe serves him for a bellows, and a pair of pincers, a hammer, a file, and a small mallet, are all his tools. He makes his crucible on the spot, with clay, mixed with charcoal and cow-dung; which gives a solidity to the crucible that prevents its breaking in the fire. One shilling are the wages of the master and his servant for a whole day.

"The Shoemaker is of the most despicable caste, and is also the poorest of all the Artisans. He has not other tools than an awl and a knife; no shop for leather, or lasts. When a pair of shoes are wanted, the money must be advanced, and with this money he buys a sheepskin, which he prepares on the same day, and on the morrow brings the shoes. From the shoemaker's working in leather, and eating meat, they are held in the greatest contempt by the other Indians, who esteem them the lowest order of men. Their huts are in separate quarters, out of the towns and villages; and in the European settlements they perform the office of executioners." Sonnerat, xi. 126-8.

Fishing, as a source of trade, is little followed in Fisheries. Hindostan; there is, however, an extensive fishery on...
the Gulf of Cutch; the fish are dried, and exported on camels and bullocks to the interior. The natives here are also employed in the pearl fishery; but this kind of fishery is carried on to the greatest extent on the shores of the south-eastern extremity of India, particularly at Tuticorin, and six other villages in the district of Tinnevelly. There are two fishing seasons in the year; one in March and April, and the other in August and September. The pearls are disposed of at a fair that is held immediately after the termination of each fishing season; they are much inferior to those procured in Ceylon, being disfigured by a blue or greenish tinge. Near Bombay, fishing stakes, formed of the trunks of the cocoa-nut tree, are laid down at the beginning of the fair season, in eight or nine fathoms water; they are taken up before the south-west monsoon commences. They are fixed by means of boats filled with water, attached to them when the tide is low; thus, of course, they are sunk to the bottom: and they are raised by a similar process, empty boats being attached to them, by means of which they are lifted up at the flowing of the tide.

The internal trade of India is conducted by boats, land carriers, travelling merchants, and at fairs. The boats which are used on the Ganges, and its tributary streams, are of various sizes and constructions; from Patna to Calcutta, where the navigation resembles that of the sea, both from the width of the river, and the storms which frequently arise, it is necessary to employ large and strong boats, or rather ships of upwards of 100 tons; in the higher parts of the river, the boats are made either low and deep, or flat, and clinker built. Between Calcutta and the sea, among the shallows, the boats are made without keel. Those which are used in the Indus are flat-bottomed, with square heads and sterns, low forward, high abait, and drawing only a few inches water; oars are seldom employed, but they are either dragged by men or pushed along with poles; when the wind admits it, sails are used. The materials of which these boats are constructed are very few, simple, and cheap; and the boatmen scarcely receive any wages except what will purchase them a little salt, tobacco, and clothing; grain is supplied them for food. The average rate of travelling, with and against the current, may be reckoned 23 miles a day. By the inland navigation in Hindostan Proper, salt, grain, cotton, and manufactured articles, are interchanged. It is said that the whole number of the boatmen employed in the rivers of Bengal and Bihar is nearly 300,000; most of these are also labourers in husbandry, or fishermen.

Land carriage is performed by oxen, buffaloes, and sometimes by horses; no carriages are used, their being no roads adapted for them. The owners of the cattle are generally the owners also of the merchandise they carry, as well as the drivers. One driver is allowed to four oxen. Their food is generally obtained without expense on the road side; but where buffaloes are employed, it is necessary to give them grain. The articles of merchandise which are thus transported, are grain, salt, cotton, sugar, tobacco, lusitel nut, &c. In the Dean there is a wandering tribe of carriers, called Lombalies, or Burgarahs, who interchange the commodities of this part of Hindostan for those of Bengal and the adjacent provinces. They are said to be the descendants of those camp-followers who accompanied the emperors Shah Jehan and Allum Geer, in their wars in the Dean. There are also in the Mahbatta countries, and other parts of Indis, vanjaries, or itinerant grain dealers—a singular race of people. Formerly they were never molested in the most disturbed state of the country, being regarded as sacred; this reverence for them, however, is now nearly at an end. They travel in large parties, with their grain on bullocks, brought from a great distance; but they do not depend entirely on their profits as grain dealers, nor on their returns of merchandise from the Dean to Hindostan Proper; for they occasionally become stationaries, and apply themselves to husbandry. This, however, seldom happens, except when they are unable to dispose of their grain. They also employ their leisure in weaving a stuff from hemp, of great strength and good quality; this is made into bags to carry grain in, and into large cloths to cover camels. The travelling merchants or banyans resemble the chapmen in Britain; they come in great numbers from Guzerat to Bombay, selling muslins, cotton cloths, &c. They are chiefly Hindoos; though some Mahommedans adopt the name and the profession; they are distinguished by a red turban, shaped in front like the horn of a rhinoceros. The banyans are generally rich, and carry on a stationary as well as an itinerant business. When travelling they are attended by coolies, porters, to carry their merchandise. Besides these, there are the boras, or petty chapmen, who are Mahommedans, very poor, and not distinguished by their honesty. They travel about the country with an almost infinite variety of small and cheap articles in their boxes.

There are weekly markets over most part of Hindostan Proper, but they are not common in other parts of India. At these there is a considerable interchange of commodities, but, of course, confined to the vicinity of the place where the market is held. The fairs of Fairs of Hindostan are of infinitely greater importance. The Cooloo most celebrated are those of Cooloo, Hurdwar, and Nolucky Hant. The fair of Cooloo, in the province of Orrisa, is attended by the traders of the inland parts of Hindostan, particularly those of Berar, and the traders in salt and European commodities from the sea coast. During the months of January, February, and March, the former arrange their caravans, and bring their merchandise, which consists chiefly of cotton, on bullocks to Cooloo. Here they are met by the traders from the sea coast. Factors are employed to transact the business among them; and they also supply them with huts, food, and other necessaries, during their abode. The commission of the factors is one per cent. Nearly all the business is carried on by factors. The fair breaks up about a month before the commencement of the rainy season. The traders then depart; but the factors are stationary.

The common fair at Hurdwar, the place where the Ganges enters Hindostan, is held annually; but every other year, twelve years there is a fair here, at which are assembled a much greater number of people than at any other fair in the world. Many of these, indeed, perhaps the largest portion of them, visit Hurdwar from motives of superstition, and as a place of pilgrimage, which will be afterwards noticed; but great numbers are also led hither from commercial motives. At the annual fairs, it is computed that between 200,000 and 200,000 people are collected. At the fair every twelve years, there are often a million; and in April 1809, it is supposed there were assembled at Hurdwar, from every part of Hindostan, from the confines of China to those of Persia, Hindoos of every description, amounting to two millions of persons. An immense variety
Statistics of articles are sold at this fair. Caubul, Candalhar, Multan, and the Punjab, supply horses, mules, camels, tobacco, antimony, assafetida, and dried fruits of all kinds. Cashmere, and the country of the Seiks, send shawls, and other goods of that description. Spotted turbans, looking glasses, toys, with various manufactures in brass and ivory, are supplied from Jeypoor. Shields from Rohilcund, Lucknow, and Silhut; bows and arrows from Multan and the Doobah; rock-salt from Lahore; baftas and piece goods from the Punjab; and cotton and woollen goods, cooza-nuts, &c. from the provinces of the East India Company. The most frequented place in the fair is the bed of the river, for at this season of the year it is almost dry. The bargains are conducted and settled without a single word being spoken: a cloth being thrown over the hands of the parties, they communicate with each other by touching the different joints of the fingers, and thus effectually prevent those near them from gaining any information. Before the British gained possession of this part of Hindostan, heavy duties were levied on the cattle brought to this fair; but these are now taken off; neither are any of those scenes of tumult and bloodshed, which formerly always disgraced it. The fair at Nolucky Hant, in the pergunnah of Bowa! in the Dacca district of Bengal, is held annually for the space of nine days. Here the weavers assemble to purchase their annual stock of trade; and it is computed, that the business carried on there frequently amounts in value to three lacks of rupees.

The following list of the principal articles exported and imports into those places from India, is taken from papers printed by order of the House of Commons:

Exports from India:

Great Britain.

- Piece goods, indigo, salt petre, opium, cassia, lyna.
- Imports.
- Raw silk, cotton, camphire, pepper, rice, sugar, turmeric, precious stones, elephants' teeth, drugs, gun, ginger.

Denmark.

- Piece goods, sundries.

Lisbon.

- Piece goods, indigo, grain, cassia buds, drugs, cotton.

America.

- Piece goods, sugar, indigo, cotton, camphire, ginger, seeds, hemp, flax, canvass, gunnies.

Coast of Malabar to and from the other parts of India.

- Piece goods, sugar and jaghery, raw silk, cocoa-nuts, pepper, drugs, elephants' teeth, cochainal, woolens, copper, iron, steel, betel nuts, liquors, dates, grain, embroidery, eopra, gunnies, ghee, spices.

Northern parts of Guzerat.

- Piece goods, sugar and jaghery, raw silk, cocoa-nuts, pepper, drugs, elephants' teeth, cochainal, woolens, copper, iron, steel, betel nuts, liquors, dates, grain, embroidery, eopra, gunnies, ghee, spices.

Sural.

- Raw silk, piece goods, sugar, betel nuts, cochainal, copper, tin, iron, woolens, elephants' teeth, liquors, pepper.

Bombay.

- Cotton, piece goods, pepper, grain, fruits, betel nuts, provisions, spill, naval stores, sandal wood, chillies, tin.

Coromandel Coast.

- Grain, piece goods, raw silk, sugar and jaghery, opium, seeds, ginger, courass and gunnies, long pepper.

Northern Circars.

- Piece goods, sugar, silk, opium, canvass.

The commerce of India is generally considered under two grand heads; viz. that which is carried on with Europe and America, and the "coasting trade," or that which is carried on from one part of India to another; and from India to the ports of the Indian islands, China, the Arabian and Persian Gulfs, and the east coast of Africa.

The Indian commerce to Europe is almost entirely carried on by Great Britain; and, till within these two years, it consisted of the commerce of the East India Company. That which is called the "privilege trade," established by an act of Parliament in the year 1793, by which the Company were empowered to grant licences to individuals to trade to India; and, lastly, the private trade, or that enjoyed by the commanders and officers of the Company's ships. Since the trade to India was thrown open, a considerable capital and amount of tonnage have been embarked on it by individuals; but the only particular respecting this branch of the trade officially known at present is, that there are employed in it upwards of 180 vessels, most of which belong to London.

The Hindoos constitute the great mass of the population of India. Their features and persons seem to mark them out as a peculiar race. Their hair is long, deep black, and by no means coarse. Their nose and lips resemble those of the European. Their eye-brows are full, especially in the men. The eye itself discloses a tinge of yellow in the white of it, while the iris is black; but it possesses little animation or intelligence. The form of their face is oval. In the northern provinces of Hindostan the men are strong and muscular. The south of Lahore they are generally delicate, and comparatively weak in the structure of their frames: even these, however, can undergo great fatigue. In the north their stature approaches that which is most common in the middle and south of Europe; in the south of Hindostan it diminishes sensibly, and in some parts it is very low. The Banians of Guzerat are reckoned the handsomest people in Hindostan; and some of the lowest castes, especially those whose business it is to remove all kinds of filth, and to bury and burn the dead, are deemed the most ugly. The female Hindoos of the higher castes are distinguished by the polish and softness of their skins, and by their fine long hair, black eyes, extended ears, and astray delicate persons. Those of the inferior castes, however, are generally of small stature, and by no means handsome.

The most singular and striking feature in the character of the Hindoos, is the permanency of their religion and customs. In almost every respect, these are the same now as they were in the most ancient periods of the history of India, of which we possess the most faint knowledge. It is supposed, however, by many authors, that the religion of Beothus, which still prevails in the Birman empire, Ceylon, &c. was in very remote times the prevalent religion of Hindostan. At present it is the Brahminical. Brahma, the creating power; Vishnu, the preserver; and Siva, the destroyer, are their three greatest deities. Since the creation of the world, however, Brahma interests himself little with mundane affairs. He is regarded as the father of legislators; since from his ten sons all science and laws proceeded, while he himself was the author of the Vedas. Of his sons, Menou is the most celebrated. From him the Hindoos derive the institutes which bear his name. Brahma is represented with four hands, and with a crown on his head. The image of the flamingo, on the wings of which he is supposed to fly, is constantly placed near his statue in the temple. His wife, whose name is Saraswatie, is regarded as the patroness of learning. Vishnu, whose province it is to preserve and protect mankind, is represented as constantly attended by an eagle, or a large brown kite, and having four hands and a number of heads, emblematical of his omniscience and omnipotence. He is said to have passed through ten different incarnations, in all of which he destroyed the enemies of the human race. His wife, or female favourite, is Sree, the goddess of fortune and plenty. Siva is worshipped not only as a destroyer, but also as a reproducer. His principal characters are Budra, Iswara, and Mahadeo. As the first, he is cruel; as the second, he is worshipped as the lord of all; and under the third name, he is known in the mountainous parts of India. He is a great favourite with the common people. He is generally represented with only one head; the number of his hands varies from four to thirty-two. Round his neck there are twenty-four human skulls. His hat is the skin of the tiger or elephant. His wife, Parvati, is the goddess of time, and the punisher of evil doers. Besides these great deities, there is a number of inferior ones, the principal of whom are those who preside over death and hell. The gods of fire, of medicine, of the wind, and of the atmosphere. Ganessa, whom Sir William Jones justly compares to Janus, is invoked the first, by the Brahmins, in all sacrifices. His name, and that of Sarasarwatie, appear at the beginning of all writings; and his statue is placed on roads, and at the boundaries of villages, &c. There are two great sects among the Hindoos; the worshippers of Vishnu, and those of Siva. Formerly the worship of the former appears to have predominated on the Coromandel coast, while, on the opposite coast, especially in the neighbourhood of Bombay, that of Siva prevailed. The followers of Vishnu distinguished themselves by painting their faces with a horizontal line; the followers of Siva draw a perpendicular line. The gopah chundon, a white clay, taken from a holy tank near Pois in Guzerat, and chalk from the vicinity of the celebrated temple of DwaraC in the same province, are used for this purpose, as well as distinguishing the different castes. There is, however, very little difference in point of religion between these, or any other Hindoo sects.

Vishnu is believed to have undergone nine avatars, or incarnations; the most celebrated is the eighth, when he appeared as Kriahna, and, by his victories, obliged the Hindoos to substitute the offering of images instead of human sacrifices, and milk for blood. The tenth incarnation of Vishnu has not yet taken place. The religion of the Hindoos is contained in their sacred books, called Vedas, the divine authority of which, however, is rejected by the Jains in the south of India,—a sect who differ in some important tenets from those who follow the Brahminal religion. All the Hindoo sects believe in the immortality of the soul, transmigration, and a future state of rewards and punishments; but their faith in these important points is intermixed and debased by the most absurd legendary tales, and mystical allegories.

The most ancient accounts which we possess respecting Hindostan, represent the inhabitants as divided into four castes, which still subsist. 1st, The Brahmins, who proceeded from the mouth of Brahma at the same time that he produced the Vedas; hence their province is to pray, read, and instruct. 2d, The C cheperees, from the arms of Brahma, whose province it is; by strength and military prowess, to protect from ill: The Vaisya, or Brice, from the belly or thighs, whose province it is to supply the necessaries, comforts, and luxuries of life, by agriculture and commerce; and, 4th, The Sudras, from the feet, who are doomed to labour. Besides these, there are the Pas cers or Chaudolas, who, having lost their caste, are held in the utmost abhorrence, and treated with the utmost indignity by all the other castes.

The Brahmins are subdivided into ten great classes, Brahmin.
and these are further subdivided according to the districts they are born in, and the families from which they are sprung. The Brahmans of Malabar will neither eat nor drink with the Brahmans of other parts of India; whereas the Brahmans of the north, especially the Hiaga Brahmans, do not scruple to cultivate the ground, to trade as merchants, and to eat fish. Although the Brahmans are not permitted to exercise the sovereignty over them, yet they are of a higher rank than princes. The laws, religion, and prejudices of the Hindoos, alike invest them with very great privileges and immunities: no greater crime can be committed than that of murdering a Brahm. He pays only one per cent. per month interest for money, whereas the second caste pays one and a half; the third two; and the fourth five: if he finds what belongs to a stranger, he keeps the whole, or five-sixths of it; whereas another person finding his own, is obliged to give up a part of it. All the priests are chosen from this order; they may also become secretaries and accountants. Some of the divisions of the Brahmans deem it unlawful to destroy animal life, or even to eat eggs; others feed on fish or fowl, but not on animal food. The following extracts from the ancient Hindoo laws will further illustrate the comparative state of the Brahmans and the lowest castes. "If a Sudra reads the Vedas to any of the other three castes, or listens to them, heated oil, wax and melted tin, shall be poured into his ears: if he gets them by heart he shall be put to death: if he spits on a Brahm, his lips shall be cut off. A Sudra, Brice, or Cheoperuce, guilty with a woman of the Brahm caste, who has a master, shall suffer death, by mutilation and burning. A Brahm guilty with a woman of any of the castes, who has a master, to be fined from 8 to 16 rupees. The shadow of a Parian passing over victuals, milk, or even water, defiles it." The institutes of Menou expressly declare that the abode of a Parian must be out of the town: he must not have the use of entire vessels; his cloaths must be the mantles of the deceased: he must continually roam from place to place, carry out the corpse of every one who dies without kindred, be the common executioner, and receive his food in potsherds, but not by the hands of the giver. No Hindoo is allowed, by his religion, to quit the caste in which he was born. Tippoo forced 12,000 Brahmans of the coast of Malabar to swallow beef broth, in consequence of which they lost their caste, became outcasts, and were either starved to death, or committed suicide.

Almost every action in the daily life of a Hindoo is prescribed by his religion; there are rules for diet, and for the manner and time of eating: he must pray thrice a day, morning, noon, and evening. The sipping of water is indispensably necessary. All his ceremonies and religious acts, and running water is always preferred. The Gayatri, which is regarded as the most holy text in their sacred books, is repeated a hundred or a thousand times, according to the magnitude and the variety of the sins to be expiated. In ancient times, animals, and even human beings, were sacrificed to their gods; but, with the exception of the Ghattaries, who on great occasions choose a human victim, and always sacrifice animals; only fruits, flowers, incense, and money, are offered in sacrifice.

Holy places. There are 28 holy rivers, dedicated to one or other of their great deities, beginning with the Ganges, and traversing the whole continent to the Indus; but the virtues of the Ganges are universally allowed to be pre-eminent. Its water is conveyed to distant parts; and the dying are often brought to it, that, with their feet in it, they may have a happy passage out of life. Holy places. If persons think of it, or invoke it, when they bathe in any other water, they will still derive all the benefits of its virtues. The Brahmans also represent four confluences of rivers, or prayaas, as sacred: That at Allahabad, where the Jumna flows into the Ganges, is the largest and most holy. Many pilgrims to this place annually drown themselves, being conducted to the middle of the river, and then sink, with pots of earth tied to their feet. There are also a great number of holy places in Hindostan. The following are some of the most distinguished: 1st, Benares, and the district ten miles round it. 2d, Oude, where Rama was born. 3d, Metta, famous for the birth of Krishna. 4th, Hardwar, already noticed for its great fair; this is frequented by the Gossains, or worshippers of Siva, who are distinguished by a wrapper of cloth, dyed with red ochre; the Bairajies, disciples of Vishnu, who are distinguished by two perpendicular stripes of yellow ochre or sandal on the forehead, and a string of beads round the neck; the Udasses, the followers of the founder of the Sikh sect, who are distinguished by a conical cap and fringe; and the followers of Mahadeva, who have a longitudinal slit in the cartilages of the ear. The period of bathing is when the sun enters Aries; and every twelfth year, when Jupiter is in Aquarius at this time, the concourse of people is greatly increased. No particular ceremony is observed in bathing. 5th, The Hindoos regard all Cashmere as holy land. 6th, The famous pagoda of Juggernaut, in the province of Orissa, is another place of great sanctity. The popular belief is, that the body of Krishna was carried there by an inundation from the vicinity of Surat. At Juggernaut, a Brahm may receive food from the hands of a Sudra. The idol Juggernaut is placed on a throne, which is raised on a car 60 feet high; and it is said, that many of the pilgrims who resort to this place throw themselves under the wheels of this car, as it is dragged along. The number, of those who come to die here is so great, that for 50 miles the ground is strewed with human bones. All persons, except certain devotees, are obliged to pay a tax before they enter the temple. From the 1st of May 1806 to the 50th of April 1807, this tax produced 317,490 sica rupees. The annual expenditure of the temple is estimated at 55,000 sica rupees, which arises from lands and villages, and an allowance of 20 per cent. from the produce of the tax. The most holy and frequent periods of pilgrimage are in March and July. 7. Gay, in the province of Bhar, which is esteemed the birth-place of Buddha, is a place much resorted to by pilgrims. The tax levied on them by the Bengal government, amounts annually to about 1½ rupees. See Juggernaut. 8. Dwaraca, in the south-west extremity of Guzerat, which was long the residence of Krishna, is on that account much resorted to. The ceremonies consist in bathing in a sacred stream—in receiving a stamp impressed with an iron instrument by a Brahm. On this instrument are engraved the spell, the ring, and the lotus, the insignia of the gods. A pilgrim may receive not only his own stamp, but stamps on his body for his friends. Lastly, The pilgrims visit the isle of Bate, where there is an image of Krishna. For all these he pays a fixed sum. It is computed, that the revenues of the temples here amount to a lack of rupees, and that 15,000 pilgrims annually resort to Dwaraca.
race. There are several other places of pilgrimage, particularly at Parkur, to which place 70,000 pilgrims annually go, to see an idol made of marble, which, after the ceremonies are performed and paid for, is carefully concealed in a spot known only to a few. And at Sagur island, which lies at the junction of the Palicat branch of the Ganges with the ocean, many of the pilgrims used to sacrifice themselves or their children to theigators and sharks, which abound there; but in 1802 the practice was abolished by Lord Wellesley.

It would carry us far beyond our limits to notice all the various superstitious opinions and practices of the Hindoos. Some, however, may be very briefly touched upon. If the bodies of those who have not been careful, during their lives, to secure the pardon of their sins, are thrown into the Ganges, they will be allowed to transmigrate in such another form as will at last bring them to heaven. The souls of the deceased may also be released from punishment, if their friends will put on a stone, rendered sacred by having been impressed by Vishnu, a certain paste, and at the same time repeat the name of the deceased. The painful distortions and tortures to which the Jognis subject themselves, are too disgusting to be related, and could not be credited except on indubitable testimony. Different kinds of suicide are held by the Hindoos to be meritorious, viz., starving; covering themselves with cow dung, and setting it on fire, and thus being consumed; burying themselves in snow; and cutting their throats at Allahabad,—to this last species of suicide, performed at the eclipses of the sun and moon, great wealth is promised in a future state. Sur, is the art of predicting events, by observing in what manner the breath issues through the nostrils. Akum, teaches what is contagious and hurtful, and what advantageous. Shooghun, is the art of discovering what is happening, or will happen, by observing the motions of birds. Keywall, are omens learned by throwing dice. Samding, by observing the form of the limbs, their motions, and the lines and moles on the body. Garul, is the art of repeating incantations for recovering a person-stung by a serpent. Inderal, includes the art of necromancy, talismans, and plight of hand.—The following diseases are regarded as punishments for crimes in a former state: Lameness, for having kicked a Brahmin a fever, for killing an innocent Chichere: a cough, for killing a Brahmin: For these punishments the expiations are presents of gold to Brahmins.—Some of their superstitious practices have already been described: A few others may be noticed. The practice of the widow burning herself on the funeral pile of her husband, is well known. There are nine kinds of trial: by ordeal—by the balance—by fire—by water—by poison—by the cow, or drinking of the water in which idols have been washed—by rice—by boiling oil—by red hot iron—and by images.—Infanticide was practiced by many tribes of Hindoos; by some, their children's lives were devoted to the sacred waters. Other Hindoos, of high caste in Benares, on a prospect of being unable to provide suitably for their female children, were induced, not unfrequently, to put them to death; and other castes of Hindoos, with a view to deter the execution of legal process, or in revenge for a supposed injury, would murder their females or their children, being persuaded, that by such means they could obtain spiritual vengeance against their adversaries.

This last species of infanticide, which, as well as the others, has been abolished by the British government, is one of the modes of which is called dherna; this is generally practised by a Brahmin, in order to obtain Dherna, or to enforce a petition. For this purpose he places himself before the door of the person from whom he wishes to obtain his object, and threatens, if he perseveres in refusing it, that he will put an end to his life by a dagger, or poison, which he always has in his hand. The Brahmin, as well as the person thus besieged, fast, so that the latter is almost always obliged to yield. Another mode of dherna, which is employed to recover property, is by the person standing up with an enormous weight on his head, which he sweats to support till he attains his object. But the most desperate species of it is that called koor; a pile of wood is erected before the door of the besieged party, and on this a cow, or an old woman, is placed; the pile is set fire to, unless the request is granted. These species of dherna are common in Hindostan Proper, and in some parts of the Deccan, especially among the Mahrafla tribes; but they do not appear to prevail in the southern parts of India.

At Surat there is an hospital for animals, supported by the superstition of the Hindoos; not only quadrupeds and birds are received into it, but it has also wards for bugs and other vermin, which are carefully nourished; this is perhaps an extreme instance of the superstitious dread which the more rigid Hindoos entertain of destroying animal life; but the practice of sweeping the ground carefully, and very gently, in order that no living being may be trod upon, and of constantly keeping gauze before the mouth, that no insect may be inhaled by the breath, are by no means uncommon among the more devout Brahmins.

The religion of the Hindoos strongly enjoins marriage as a sacred duty; but as strongly reprobrates the marriage of any of the younger branches of a family before the elder; marriages usually take place when the children are 11 years old. Polygamy is permitted, but seldom practised, except where the wife is barren. As a powerful religious prejudice or feeling prevails in favour of leaving a representative, a third marriage is even allowed; and if all are unfruitful, a child is adopted. The marriages of the Hindoos are celebrated with great pomp and expense, and are attended with a vast number of ceremonies: the most material part of the ceremony consists in the bride's taking seven steps, for each marriage is not complete till the seventh step is taken. In the evening the bridegroom points out to his bride the polar star, as an emblem of stability; for three days they remain in the house of the bride's father, where the marriage is celebrated; and then a formal entry into the bridegroom's house takes place: many ceremonies attend this, the principal of which is the liberation of a cow, which had been tied up in the northern side of the apartment, by a barber, who attends for that purpose, and exclaims, "the cow! the cow!" The Hindoos make presents to the fathers of their brides, instead of receiving dowers. All persons bearing the sixth degree of affinity, or even the same family name, are forbidden to intermarry.

As it is deemed of such high importance to have Birth children, the wife, during her pregnancy, is attended to with great care; when she has attained the seventh month, a particular festival is celebrated, and another when she is delivered. As soon as the child is born, it is bathed with cold water; information is immediately sent to the magistrate, in order that it may be added to the list of those who compose the caste to which
it belongs; its birth day is also entered by the Brahmins, in registers kept by them in the temples, of births, marriages, and deaths. The astrologer next foretells its destiny. On the 10th day after the birth, when the period of purification is complete, a name is given to the child, from the elements, plants, or stars, or from the symbols by which they are represented. On this occasion there is a burnt-offering of wood, rice, and butter. Water is consecrated by the Brahmins, and with this the child and every person present is sprinkled. If the parents are too poor to pay a Brahmin, the name of the child is performed by the chief of the caste.

New ceremonies, with presents to the Brahmins, take place when boys arrive at the age of seven or nine,—the period at which the three first castes receive the string, which is one of their distinguishing marks. In cases of adoption, the child is placed on a large brass plate, in the house of the person who means to adopt it; and after the husband and wife have repeated a certain form of words, the ceremony is finished by their drinking water mixed with saffron, and pouring part of it on the feet of the child; if they afterwards have children, they adopt child resolutely, as if he had been their own, and first born.

There are schools in almost every village for teaching, reading, writing, and accounts; the children sit in the open air, under the shade of a cocoa nut, or other tree, and trace on the sand, with the fore-finger of the right hand, the elements of the alphabet, and then smooth it with the left hand. This mode of teaching, like all the other customs and practices of the Hindoos, is very ancient, being mentioned by Megasthenes. The village schools are only day schools; each child pays one or two annas per month. In opulent families teachers are retained as servants, as the children of respectable Hindoos seldom go to school. Persian and Arabic are taught for the most part by molavies, who frequently have a few scholars in their houses, whom they support as well as instruct. When the children have made a tolerable progress in writing on sand, they begin to write on palm leaves, with an iron pen, or style. When the teacher enters the school, his pupils throw themselves down at full length before him, and place their right hand on their mouth, from which it is not withdrawn till he gives them permission to speak. In some parts of Hindostan, there are schools supported by voluntary contributions, or by the produce of land. In the 24 Pargannahs, a small district in Bengal, which contains only about 882 square miles, there are 190 seminaries of this description, in which Hindoo laws, grammar, and metaphysics, are taught; the annual expense is estimated at 19,500 rupees. When the education of a Hindoo is completed, lie commences the business of his father.

Death and funerals.

The ceremonies which are practised in cases of illness, which it is anticipated will prove fatal, are numerous, and some of them of such a nature as seem intended, as they are certainly calculated, to hasten the death of the patient: their professed object is to secure his salvation. After these ceremonies have been performed, it is deemed unholy to live; and the patient, if he does survive, loses his caste, and becomes a pariah. At the approach of death, he is laid on eusa grass, in the open air, for it is deemed unholy to die in the house; or, if the Ganges is near, he is carried to its banks, and there bequeathes part of his property to the Brahmins. Water and mud from this river are thrown upon him, and the salagrama stone, already described, is placed near him. Several other ceremonies are performed till he dies, when another set of ceremonies commence. All the relations repair to the house of the deceased. Cries, lamentations, dishevelled hair, beating of breasts, and rolling themselves on the ground, are common among the women. After all the ceremonies are performed, preparations are made for the funeral: the body is washed; the sign of the caste is marked on the forehead, and betel is put into the mouth. It is carried to the place of funeral by pariars; and when it arrives there, the nose and stomach are pinched, water is flung in the face, and tom-toms and trumpets are sounded, to perceive if it be really dead. The funeral ceremonies are always performed at night. The followers of Siva bury their dead, whereas those of Vishnu burn them. The burying grounds are out of the towns, generally near a river or tank. Each caste has their separate burying-place. As a dead body is supposed to pollute not only the house in which it is, but also the neighbourhood, all who live in the same street abstain from food till it is removed. It is not carried out by the door, but through a hole in the wall made for that purpose, in a sitting posture. After the funeral, the nearest relation returns to the house of the deceased, preceded by a person bearing a staff, to drive away evil spirits. A variety of ceremonies are then performed for a few days; and till these are completed, all the relations are restricted to one meal a day; and in cases where the body has been burnt, they are not permitted to sleep on a bedstead, or adorn or perfume their persons till the ashes are gathered. This cannot be done till food has been offered to the manes of the deceased, the Brahmins have been fed, and the officiating priest received his fee. The ashes are gathered according to a prescribed form, and then thrown into the water. Ninety-six formal obsequies are performed in the course of the year, besides daily oblations to the manes. The mourning of the Hindoo is very simple, and in some respects resembles that of other Asiatic nations. It consists in shaving the hair; covering the head with the linen which they usually wear on their shoulders; and abstaining from the use of betel. As this last is deemed very annoying, the abstinence lasts only for a few days.

The customs of the Hindoos which we have described, are immediately derived from, and intimately connected with, their religion and superstitions. There are others, however, to which we must briefly advert. The extreme fondness of the Orientals for formal and minute ceremonies in their interviews with each other, is well known. The most important of these ceremonies, practised especially among the Mahrrata tribes, is called milling. A detail of all the minutiae would be tedious and uninteresting. It takes place only between two persons of equal rank, and generally when they are in the field with their troops. A spot midway between their camps is selected for the interview; and towards this spot, two splendid and magnificent cælastes set off, as nearly as possible, at the same time. As soon as they come in view of each other, the titles, rank, &c. of the parties, are solemnly and loudly proclaimed by officers kept for that purpose. The person to whom the honour is intended, then first lights from his elephant, and mingles with all the attendants of his visitor. The ceremony consists in embracing; laying the head first over the right, and then over the left shoulder, and making a salute by lifting the hand up to the forehead. No business is transacted on these occasions. When the chiefs visit each other in their respective camps, valuable presents are given; and on
all occasions of visiting among people of all ranks, be-
tel is invariably served round; without it no person
ever leaves the house of the person he visits.

These are some customs of the Hindoos which bear
a striking resemblance to some of the customs of Eu-
ropceans. During the festival of Huli, which is held in
the month of March, the custom of what we call mak-
ing April fool's is practised; and on one of the festi-
vals of Bhavani, which occurs about the beginning of
May, the caste of cow-keepers erect a pole adorned
with flowers, round which they perform certain cer-
emonies, very similar to those which are performed
round the Maypole in England.

The Hindoos are much addicted to gaming, espe-
cially cock-fighting; besides cocks, quails and other
birds are trained for this purpose. At these games, the Hindoos will frequently lose all their ornaments; and even part of their dress. Chess is a favourite play with them, and appears to have been played in the most remote periods of their history, but in a much more complicated
form than at present. The mode of playing it, in
use among the modern Hindoos, very strongly resembles the European mode. Dancing, tumbling, slight of
hand tricks, and wrestling, are favourite amusements
with the Hindoos. Dancing, however, is not permitted,
except to a particular caste, who are trained to the art.
The dancing-girls, or devadassis, are generally of agree-
able persons and countenances; their motions display
great grace and ease, but are not always scrupulously
decent. They devote themselves to the honour of the
gods; but this does not prevent them from hiring them-
selves out to those who wish for their exhibitions; and
accordingly their dancing forms part of all great enter-
tainments. They are adorned with jewels; and their
robes, which are made not to impede their motions, and
to display their persons to the greatest advantage, are
hung with little bells. There are also male dancers,
but these confine themselves to pantomimes. Surat is
famous for its dancing-girls. The feats of the jugglers
far surpass any that are practised by those of Europe;
in connection with them may be mentioned the exhibi-
tion of dancing snakes, which are handled without the
least danger. The feats of the professed wrestlers are
very surprising, exhibiting a degree of strength and
agility, and at the same time of elegance and grace, in
their attitudes, of which, it is said, those who have not
witnessed them can form no adequate idea. But the
most favourite amusement of the Hindoos consists in
hearing the recital of poems or histories. These are
recited by persons who make it a regular business;
sometimes they merely recite, at others, a kind of re-
citative is performed.

The general character of the Hindoos varies much in
different parts of India. Even under the Bengal
presidency, there are two distinct descriptions of Hindoos. Berar Patna, the Bengalees, as they are called,
are weak in body, and timid in mind: and that timid-
ity is accompanied, as usual, by servility and fraud.
This class seem to diminish, both in their bodily
strength and mental qualities, as they approach the
coast; those below Cutchta being reckoned the most
abject and imbecile in body and mind, of all the Hindoos, subject to the British government. As soon,
however, as Bahar is entered, or rather the district of
Benares, a different race appears. Throughout all the
territories in that quarter, subject to the Company, and
the Nabob of Oude, the Hindoo inhabitants are dis-
tinguished, not more by their lofty stature and robust
frame of body, than by their courage, and mental quali-
ties. The great part of the army on the Bengal
Establishment, is composed of these men; and it is re-
markable, that there are few corporal punishments in
it, the slightest reproach being felt as severely as the
greatest punishment is, among soldiers of European
nations. On the coast of Coromandel, the Hindoo is
inferior, both in bodily and mental qualities, to the
Bengalee; the other inhabitants vary much in their
character. The Maharrattas are bold, active, and insi-
dious; among the higher classes, and especially among the Brahmins, there is frequently displayed a very ex-
traordinary degree of urbanity, proceeding, not from
feeling, or even politeness, so much as from hypocrisy.
Their command of temper and countenance is indeed
astonishing.

One of the peculiarities of the Hindoos, recorded by
Arrian, &c., is their not eating animal food; and this
peculiarity still exists. Throughout the southern parts
of India, however, fowls are a common article of diet
with the lower castes; but in the northern parts, they
are seldom eaten except by the Mahommedans and Eu-opians. Fish is eaten even by some of the Brahmins,
as has been already noticed; but in all cases where fowls
or fish are eaten, they are mixed with a very large por-
tion of spiders. Vegetables are their principal diet, in
all cases most plentifully mixed with vegetables. Cereals are used by some of the natives of northern Hindoostan,
but in no great quantities. Rice, barley, and dif-
ferent species of pulse, made into cakes, is the usual
food in Hindostan Proper and the Deccan; —raggy,
in Southern India. Mrs. Graham thus describes the mode
of making rice cake:—After the rice had been pound-
ed by a mill already noticed, the woman, whom Mrs.
Graham observed, carefully washed every vessel, though
apparently clean before, "and then mixed her rice-
flour with milk, water, and salt, when she beat it be-
tween the palms of her hands till it was round, and
then baked it on a round iron plate, such as is used in
Scotland for oat cakes. Besides these cakes, she pre-
pared a few heads of maize, by rubbing off the chaff,
and laying them in the fire to roast for the family sup-
er. At the next hut, the woman was grinding mis-
sa, or curry stuff, on a flat smooth stone, with another
shaped like a rolling-pin. Less than an English half-
penny procures enough of turmeric, spice, salt, and
ghee, to season the whole of the rice eaten in a day by
a labourer, his wife, and five or six children. The ve-
tegetables and seids he requires are found in every
hedge." Journal, p. 20. The Hindoos eat their food
generally from dishes made of the leaves of the plan-
tain. In Bengal, a single leaf is sufficiently large for
this purpose; but in places where they are not of a
proper size, they are fastened together by people cal-
d barhi, who make it a particular business, to be
found in every village, and receive their allowance of
wages from the Zendemar and Ryot, in the same manner
as the Brahmin, bard, &c. The potter, also, who makes
the earthen vessels used for cooking the food, or hold-
ing water, receives his allowance of grain or of money.
Water is the only drink of respectable Indiains; toddy
and other intoxicating liquors are seldom drank except
by the very lowest castes. In such a hot climate, it is
absolutely necessary to cool the water and other liquids
before they are drank. The vessels used for this pur-
purpose are made in most parts of India, but principally
in Guzerat. Smoking is very general in the northern
parts of India; but in the Carnatic, and other parts of
the south, it is held in great disrepute. Here, taking
snuff is much more common than in Bengal. The
lower classes indeed smoke segars; but by this practice, a Brahmin would lose his caste; and even those of the Sudras, who are comparatively rich, would be dishonoured. It is scarcely necessary to state, that the religion of the Hindoos forbids them to taste any food or liquid, which has been prepared by, or belongs to persons of a different religion.

The distinctions of dress in India consist almost entirely in the fineness of the linen of which it is made. The kinds and form of their garments are the same that they were 2000 years ago, with the exception, perhaps, of the turban, the jumnah, and long drawers, which are supposed by some to have been borrowed from the Mahomedans. The ancient dress of the Indians, as described by Arrian, consisted of a muslin, cloth thrown loosely about the shoulders, and a muslin shirt which reached to the middle of the leg. He likewise notices that their beards were dyed various colours. The dress of the women at present, is very simple and graceful; a boddice, or close jacket, with half sleeves, fastened behind, and generally made of coloured brocade, covers their breasts, without concealing their form. The shalise, a wide and long piece of coloured silk or muslin, is wrapped round the waist, in such a manner as to leave part of one leg bare; on the other side, it reaches below the ankle, which it covers with long and graceful folds: in front it is gathered up; and the upper end, which crosses the breast, is sometimes thrown over the head as a veil. The hair is generally tied in a knot on the back part of the head, and the roots are often stained red. The hands and feet are covered with bracelets and rings; and a valuable jewel is frequently fastened in the nose. The large black eyes of the Hindoo women are lengthened out at the corners by black streaks; and the palms of their hands, soles of their feet, and their nails, are stained red with the juice of the seeds of the henna plant. The dress of the men is either in what is considered as the ancient Hindoo fashion, or in that which resembles the dress of the Mahomedans, and which, as we have already mentioned, is supposed to have been introduced by the Moguls. The former consists of a piece of cloth fastened round the waist, reaching down to the knee. Round the body another piece is folded, in different modes, according to the fancy or taste of the wearer. A piece of fine muslin envelopes the head. In the other fashion, wide drawers reaching to the ankles are worn, together with a long robe, which is crossed over the breast, tied round the loins by a scarf. A kind of turban is worn on the head. The Indians who wear this dress are distinguished from the Moors, by the circumstance, that their robes are fastened on the left side of the breast, whereas those of the Moors are fastened on the right side. Sandals, or slippers, are worn on the feet, the latter having a long crooked point. The Hindoos generally shave their heads and beards, with the exception of a lock of hair on the back part of their head, and a small pair of whiskers. The different castes are distinguished, with respect to their dress, by strings worn round the shoulders. The string of the Brahmins is composed of threads of cotton; the number, mode of spinning and dyeing, and of knotting, are most especially marked out by their religion. The Chettee caste wear a string composed of fewer threads; the Brice have one with still fewer threads; but the Sudras are not permitted to wear any string.

The houses of the great mass of the Hindoos are made with little trouble or expense, and in a very short time. A number of mats, formed of the leaves of the palm or cocoanut tree, are spread over a roof made of bamboo laths, whilst the bamboo unspilt, forms the supports of the house. In it, a Hindoo can live for six months in those parts of Hindostan which are not subject to much rain. The houses of a better description have walls made of mud, which the intense heat of the climate soon renders sufficiently hard. These walls are raised to the height of six or seven feet; the covering consists of rushes or rice straw. On the west of India, the practice of covering houses with tiles is general. Different styles of building prevail to the north and the south of the Krishna. To the north of this river, the roofs are in many cases pitched and thatched; to the south, those of the lower classes are flat roofed, and covered with mud and clay. The houses in the south of India, also, usually consist only of one storey, inclosing a court, with a small gallery supported by slight wooden pillars. The houses of the more opulent consists of two storeys, and are sometimes built of brick. The upper storey is set apart for sleeping, studying, or performing any business in which they do not wish to be interrupted. On the floor of a gallery which runs out towards the street, and is raised a little above it, the palanquin bearers, and other attendants, often lie down. The cement employed in the construction of the best houses, is composed of sugar and lime. The best sort of eari, which is used in painting their houses, is produced in North Canara.

The furniture of the houses is in general very simple. The floors of those of the lower classes are either the bare mud, or are covered with straw. The floors of the apartments of the higher classes are covered with mats and carpets, over which is frequently laid white cotton cloth. The other articles of furniture in the common houses consist of a bed-frame, on which a mat is placed; a few flat dishes of copper or brass; a brass drinking vessel with a spout; a pot in which they boil their rice; a lamp; and a large wooden mortar to pound the rice. A Hindoo has no table; he eats alone upon the bare ground. The whole of what may be called his table service consists of a brass basin and an earthen plate.

From the account we have given of the dress, food, and expence of living, it may easily be perceived that the expences of their mode of living must be very trifling; otherwise, indeed, it would be impossible for the Hindoo labourer, whose wages seldom reach five shillings a month, and is in general much lower, should be able to support himself and family. On this subject there is some curious and interesting information in the reports on the affairs of the East India Company laid before Parliament. The following table exhibits a statement of the expences and earnings of the family of a Madras labourer, consisting of himself, his wife, and five children, the eldest eight years of age, the youngest an infant.

The following is a statement of the expenses for a month of a Madras middling HIndoo family, being that of a dubash, or interpreter, who kept a hackery, or carriage, and 2 bullocks. The family consisted of 6 men, a boy of 12 years old, and 12 women; in all 19 persons.

- 20 Mercals of rice, at 1 mercal per day, at 5 mercals per pagoda: Pag. 0, Fan. 3, Cash. 0
- 30 Measures of do. at 1 measure per day, for the daily beggars, &c.: Pag. 0, Fan. 3, Cash. 0
- 50 Do. of Nutcheny is 37 mercals per month, at 8 mercals per pagoda: Pag. 0, Fan. 3, Cash. 0
- 3 Do. of doll and green grain: Pag. 0, Fan. 3, Cash. 0
- Hazar expenses, such as ghee, spices, curry, &c.: Pag. 1, Fan. 0, Cash. 0
- 500 Billets of fire-wood, and bratty: Pag. 0, Fan. 1, Cash. 0
- 50 Bundles of betel, at 1 bundle per day, at 1-30 each: Pag. 1, Fan. 0, Cash. 0
- 5 Viss of boiled nuts, at 1 fanam per viss: Pag. 1, Fan. 0, Cash. 0
- 1 Do. of tobacco: Pag. 0, Fan. 1, Cash. 0
- 9 Measures of lamp-oil, 54 fanams; 1 measure Gingeley-oil, 7: Pag. 1, Fan. 0, Cash. 0
- Sundry expenses for vegetables: Pag. 5, Fan. 0, Cash. 0

**Hackery Expenses**

- Horse grain for the 2 bullocks, 90 measures, at 3 measures per day, at 8 mercals per pagoda: Pag. 1, Fan. 1, Cash. 20
- Straw, 20 bundles, at 4 fanams per bundle: Pag. 1, Fan. 1, Cash. 20
- Hackery driver's pay: Pag. 1, Fan. 1, Cash. 20
- 1 Servant, 1 pagoda, 1 washer, 22.40: Pag. 1, Fan. 1, Cash. 20

**Cloth for the men and women for a year**

- Father and elder brother's anniversaries: Pag. 25
- Expenes of the Ponjal feast: Pag. 15

**Total expense for a month**: £200 0 0

**Total per annum**: £16 14 2
The cash is a copper coin, 37½ to a penny, coined and sent from England to India.

The following is a general estimate of the consumption of natural and manufactured produce in Bengal, Bahar, &c. supposing them to contain 15 millions of native inhabitants, and that these are divided into eight classes:

Such Hindus as can afford it, travel either in a hackery or a palanquin. The first resembles a turreted, fixed on a small cart with two wheels, with curtains round it: it is drawn by oxen. The palanquin is a couch covered with a canopy, suspended on poles formed of bamboo; two bearers take hold of the poles at each end, and will carry the palanquin at the rate of nearly six miles an hour. Caravansaries are common on most of the roads in India: they consist of three apartments; in one the palanquins are deposited; the others are intended for the travellers to sleep in; on these mats are spread: boiled rice and water is given free of expense; and other articles of Hindu diet may generally be obtained from the Brahmins who reside in the neighbourhood.

The ships and boats of the Hindus are of a very simple construction; they make little use of nails or iron work; the planks are sewed together; the seams filled up with the fine fibres of the cocoanut tree, and daubed over either with cocoa nut oil and lime, or with fish oil. In some cases, however, their ships are constructed more after the European manner.

An Indian army consists not merely of those who are to fight, they indeed compose a small portion of it, but of the wives and families of the soldiers, merchants and their servants, and adventurers of all descriptions: Every horse has two persons attached to it, besides the rider, one of whom cleans it, and the other provides the forage. The devastations created by an Indian army are dreadful; on its approach the whole population emigrates; the people of a district thus deserting their homes, are called the mula; before a British army, however, unaccompanied by Indian allies, this emigration never takes place. That the Hindus are capable of being made good soldiers, is abundantly proved by the state of discipline, firmness, and courage, to which the Sepoys in British pay have been raised.

In Hindostan all titles are connected with military power; if this is lost, the title is soon lost also. Latterly, however, great wealth and influence also confers a title, in the same manner as a learned person is saluted by the appellation of pundit.

The laws of Menou are the most ancient and most highly venerated among the Hindus. They consist of eighteen principal articles; the ten first relate to debts, deposits, partnerships, boundaries, sales, &c., and masters and servants; the eleventh and twelfth, to assault and slander; the thirteenth to larceny; the fourteenth to robbery; the fifteenth to adultery; the sixteenth to matrimonial disputes; the seventeenth to inheritance; and the eighteenth to gambling. These laws contain, besides, a variety of very frivolous rules for the most ordinary transactions of life. According to the law of inheritance, the property is divided into equal shares, two to the eldest son, one and a half to the next, and one to each of the others; to the unmarried daughters, the brothers give each a fourth of his share.

In Hindostan Proper, the Mahomedan law is the rule for the administration of criminal justice; and to this, with a few exceptions, the British government has adhered.

The supreme authority in British India, which, as we have seen, comprises, either in its direct or indirect authority, the greatest part of India, is vested in a Governor-General in council, who is appointed by the Crown and the Court of Directors: the seat of this supreme government is at Calcutta, the capital of the Bengal presidency; in each of the two subordinate presidencies of Madras and Bombay, there is also a governor and council. In the Bengal presidency, there is one supreme court at Calcutta; six courts of appeal and circuit attached to six different divisions; and forty magistrates stationed in as many different districts and cities. The territories subject to the Madras presidency are divided into twenty-one districts: those under the Bombay presidency are less numerous and less clearly defined. Besides magistrates for the administration of justice, the East India Company have collectors of revenue in all the districts. This revenue is almost entirely derived from land, salt, and opium; it amounts to about seventeen millions annually. In time of war, the troops in the pay of the Company generally amount to about 150,000, of which there are seldom more than 25,000 Europeans; the rest are native troops. The number of Britishborn subjects in India (exclusive of those in the army) is about 6000 or 7000.

The ancient languages of India are supposed to have been Sanscrit; the Pracrit; the Paisiachi, and the Magadhi; the Sanscrit is still cultivated as the language of literature, science, laws, and religion; of the Pracrit, or spoken language, there appear to have been 10 dialects; that still called Pracrit is spoken on the banks of the Sereswatie; in it great part of most of the Hindoo dramas, and many poems, are written; the next dialect of the Pracrit, named from the Cauvery, and also spoken, is supposed to be the groundwork of the modern Hindostanee; the Gaura, or Bengalee, is spoken in Calcutta, and in Bengal on the banks of the Ganges: the Mahals is used in the Circus of Tirkut; the Uriga, in Orissa; the Guzeratie, which is not unlike the Hindostanee, is spoken not only in Guzerat, but at Surat, Tatta, &c. The Tamul Malabar extends from Cape Comorin to Canara; the Mahratta prevails throughout the whole of the Mahratta territories; the Canara is spoken in the mountainous district which lies between the eastern and western divisions of the ancient Carnacata; and extends as far as Goa; the Talanga is spoken on the coast of Orissa, in Golconda, on the Krishna, and as far as the ceded districts.

The most venerated books among the Hindus are Books, the Vedas and the two great poems; only the three highest castes are permitted to read these. The Vedas treat of all the different branches of knowledge; the two great poems are the Ramayana of Valmiki, and the Mahabharat, which contains the adventures of Krishna; there are also other ancient epic poems, besides dramas and lyric poems, in high esteem among the Hindoes; of their dramas, Satcanta, or the fatal ring, has been translated by Sir William Jones and Mr. Wilkins.

The ancient music of Hindostan is supposed to have been superior to the modern, and to have been more cultivated; the modern scale comprehends seven sounds, and in the octave they reckon 22 quarters and thirds; they also divide the seven natural sounds into 84 modes. Their instruments are very loud and disagreeable; and consist principally of drums, trumpets, and pipes; in their stringed instruments, the strings are made of iron or brass wire, and the fingers of those who play on
The Hindoos were very numerous, especially in the vicinity of Cochin, where they are divided into two classes; the white or Jerusalem Jews, and the ancient or black Jews,—the latter are considered an inferior race.

Christianity established itself on the Malabar coast at a very early period. Before the arrival of Vasco de Gama there were 44 churches, all of the Nestorian persuasion, containing above 200,000 people. At present there are not above 40,000 of this persuasion; but the number of all kinds of Christians on the Malabar coast is still about 200,000; of whom 90,000 are settled in the province of Travancore. In some parts of this province Christian churches are much more numerous than Hindoo temples. A great proportion of the fishermen on the Coast are Christians.

The population of India has been differently estimated, nor is it possible to fix it with any degree of accuracy. According to Mr. C. Butter, in his letter to the Court of Directors respecting the temple of Jugrnath, 19th May 1813, the whole of the Hindoo population, as far as Cabul, is not much short of 200,000,000. This, however, is undoubtedly much too high an estimate. According to Mr. Walter Hamilton, in his *East India Gazetteer*, there are in Northern Hindostan, Hindostan Proper, the Deccan, and the South of India, 101,000,000; of which there are 53,500,000 in British Hindostan, 17,500,000 in the territories of the British allies and tributaries, 15,000,000 in the independent principalities, and the same number under the Rajpoors of Ajmeer, the Amcres of Sind, the Cabul government, the Rajahs of Bootan and Assam, &c. The Marquis Wellesley, however, in a recent debate on East India affairs, stated the population of British Hindostan at only 40,000,000; and this is probably nearer the truth. Supposing the area of this part of India to be 357,000 geographical square miles, this will give rather more than 112 inhabitants to the square mile. In the years 1800-1 and 1802, answers were sent to the Governor-General to several queries regarding the Bengal Presidency, one of which had relation to the population of its different districts. The following are the results:

**Calcutta division.**

The soil of this territory is very fertile, and is well adapted to the production of wheat, rye, indigo, tobacco, &c. A silver mine has lately been discovered above Quiatanong on the northern side of the Wabash. Salt springs, lime, blue and yellow freestone, and white clay, abound upon the River Wabash. Sea coal is found on Big River, and on all the streams which run into the Ohio. An establishment of salt works, under the patronage of Congress, has been made at the salt springs near the Wabash, which was ceded by certain Indians to the United States.

The principal rivers of Indiana are, the Wabash, which runs into the Ohio by a mouth 810 feet wide, and about 887 miles below Pittsburgh. It is navigable in spring, summer, and autumn, by batteaux drawing 3 feet water, for 412 miles to Quiatanong, and the large canoes for 197 miles higher up to the Miami carrying place, 9 miles from the village of Miami on Miami River, which flows into the south-west part of Lake Erie. White River falls into the Wabash about 20 miles below Vincennes. The other rivers are the Thieski and Plein, which unite below Lake DuPage, and form the Illinois River.

The commerce of Indiana centres in Vincennes, the capital, which is situated on the banks of the Wabash, about 150 miles from its mouth. The merchants bring their goods from Canada down the Wabash, up the Mississippi from Orleans, and down the Ohio, and up the Wabash from the eastern states.

The population of this territory in 1800 was 4875, and in 1810, 24,920. In 1800, the militia of this territory, which then embraced that of Illinois, was 2057, and the number of males between 16 and 45 was 4600. Indiana formed part of the north-western territory till January 1801, when it was erected by consent of Congress into a temporary government, with the usual powers and privileges. See Morse's Geography, p. 205.

INDIANS, see America and Canada.

INDICATIVE, see Grammar.

INDICTMENT, in law, is a mode of prosecuting offenders in the law of England, an indictment is a written accusation of one or more persons of a crime or misdemeanor, preferred to, and presented upon oath by a grand jury.

Indictments must be framed with precision and certainty. In order to identify the person of the criminal, they must set forth his Christian name, surname, state and degree, mystery, town or place, and county. The time and place of committing the offence, are also to be ascertained; but a mistake in these points is not in ge-
nected to be material, provided the former be laid previous to the finding of the indictment, and the latter be within the jurisdiction of the court; unless in those cases where a limitation in point of time is assigned by statute for the prosecution of offenders. The offence must be set forth with clearness and certainty; and in some crimes, particular technical words must be used, else the indictment is void. Thus in treason, the facts must be laid to be done "reasonably, and against his allegiance," in indictments for murder, it is necessary to say that the party indicted "murdered" the other; in felonies, the adverb "feloniously" must be used, and in burglaries, "burglariously." In rapes, the word "raped" is necessary, and must not be expressed by any periphrasis. So in larcenies, the words "feloniously took and carried away" are necessary to every indictment, as alone expressive of the precise offence. In indictments for murder, the length and depth of the wound should also in general be expressed. In some indictments, it is likewise necessary to express the value of the thing which is the subject or instrument of the offence; as in larcenies, in order that it may appear whether it be grand or petit larceny; and whether entitled, or not, to the benefit of clergy; and in homicide of all sorts, as the weapon with which it is committed, falls, as a deodand, to the king.

In the law of Scotland, indictments are framed at the instance of the Lord Advocate, in whose name they are laid. When a private party joins in the prosecution, his name may be added to that of the Lord Advocate; but when the private party is the principal prosecutor, with concurrence of the Lord Advocate, the action is brought in the form of criminal letters. And this last is also the form generally used in prosecutions at the instance of the Lord Advocate, when the party accused is not in custody.

Indictments, in Scotland, are prepared in a syllogistic form. The major proposition states the nature of the crime, and in general, that it is severely punishable; the minor states the offence alleged to have been committed by the party accused, and avers that it constitutes the crime stated in the major proposition; and the indictment concludes, that, on conviction by the verdict of the jury, the pannal ought to suffer the punishment of the law. See Blackstone's Comment. Jacob's Law Dict. Erskine's Inst. of the Law of Scotl. Hume's Comment. Bell's Dict. of the Law of Scotl. (2)

INDIES, EAST. See INDIA.

INDIGESTION. See MEDICINE.

INDIGO, a well known and much esteemed blue dye. Under the article DYEING (where see Indigo in the Index) will be found an account of the history of its introduction into Europe, and of the processes by which it is applied in practice. Under CHEMISTRY, (see Index) will be found a minute account of its chemical properties, with brief notices of its natural history. But as the importance of the dye renders the history of it, and the processes which it undergoes preparatory to its exportation from the countries which produce it, interesting to those who cultivate or respect the useful arts, we shall, under the present article, give an ampler account of these subjects than appeared conformable to the rank which it held under those more comprehensive heads. At the same time, as even in this instance we avoid unnecessary repetitions, we advise those readers who are deeply interested in the subject, to peruse also the accounts there given.

This substance, or its basis, is contained in the isatis tinctoria, which grows in temperate climates, and has been used for imparting a blue colour to the animal and vegetable fibre. It is also contained in some leguminous plants of warmer latitudes, particularly various species of the indigofera. When it exists in small quantity along with the other constituent parts of the plant, it may be extracted by water, and detained in that mass, until a sufficient length of time to admit of being used as a dye. These plants, therefore, were, in former times, merely dried and comminuted for the market, and the processes of fermentation and exposure to an absorption of oxygen were left to the care of the dyer. The isatis tinctoria and luistinica were indeed often subjected to a partial fermentation previously to drying. In Hindostan, for thousands of years back, the colouring matter of the indigo plant has been extracted, oxygenated, and precipitated in a comparatively pure state for sale. In the plant, the basis of indigo is formed colourless, destitute of the requisite proportion of oxygen, and is then extremely liable to decomposition and destruction; but, after it has received that addition, its qualities are remarkably permanent. This property is mentioned by Dr. Bancroft, as manifested by the simple experiment of squeezing the juice of the fresh leaves on calico. The colour is at first green, but, by the influence of oxygen from the atmosphere, it is converted into a permanent blue.

This, however, only affords an imperfect, though a simple, exemplification of the principles on which the preparation of indigo depends. We shall give an account of the process by which this is effected on the large scale.

The plants from which it is produced are, 1. The indigofera anom, a large American plant, which affords indigo of good quality. 2. Indigofera tinctoria, a Chinese and Indian plant, which has been carried to America. This is less hardy, but more productive than the preceding. 3. Indigofera dyserpma. This affords the Guatimala indigo. Its produce is uncommonly fine, but less abundant; and, 4. Indigofera argentea, which affords the indigo bastard of the French. All these plants are small shrubs, which emit a small offensive to cattle. The stems with the leaves are cut, and, either immediately, or after more or less drying, are pressed down into large vats or steepers, then covered with water, which is generally cold. A slight motion, increase of bulk, and evolution of heat, are in a few hours perceived: air-bubbles rise, and patches of froth are formed on the surface, together with a violet or copper-coloured cream, which soon after acquires a fine blue; the body of the liquor becomes green, but in no degree turbid, till fully exposed to the action of the air. Instead of the peculiar smell of the recent plant, a putrescent and extremely offensive colour is generated. In the first part of this process, it has been ascertained that there is an absorption of oxygen; the gas which is separated in bubbles is carbonic acid. While the liquor first becomes green, it deposits a fine green precipitate which treated with alkalies: at a later period, it deposits, when thus treated, a substance of a light sky-blue. When the fermentation is completed, the green liquor is drawn off into the beating vat, in which it is agitated or churned by machinery. It now absorbs oxygen, and the colouring matter is formed into a flocculent substance, which is merely suspended in the fluid, while the other principles are still in a state of solution. Lime-water, or caustic alkali, is added, to promote the precipitation of the indigo, as soon as it is observed to be distinctly granulated. At this stage, the froth, from being blue, is rendered colourless by the subsiding of the blue matter. When this addition is made, a further absorption of oxygen
IND 117 IND

Indigo takes place; and, after it has settled a little, the evolution of carbonic acid wholly ceases. When the precipitation is complete, the supernatant liquor is of a clear brandy or Madeira wine colour. A greenish or olive tint is an evidence of imperfect precipitation, and arises either from its being united to a portion of carbonic acid, or its not having absorbed a sufficient quantity of oxygen, most probably the latter, as a further exposure to the atmosphere by churning causes it to precipitate an additional portion of indigo when treated with alkalis.

Great attention must be paid, in all the stages of this process, to adjust the best degree of each change. If the fermentation is too soon stopped, a part of the indigo remains unextracted. This is ascertained by the colour of the twigs, when a few are taken out and inspected. They are of a pale yellow, and tender, when they have yielded the whole. The degree of evolution of gas is also to be regulated: when the quantity is deficient, the liquor is of a yellowish green. When the fermentation is carried too far, the liquor becomes turbid, from an admixture of grosser parts separated from the plant, and the condensation and precipitation of the indigo are prevented from taking place with the due facility, and from yielding an article of genuine purity. This is more dangerous than a deficient fermentation, as not being so easily remedied. It appears from the experiments of Dr. Buxburgh, that the absorption of oxygen is essential both during the fermentation and the precipitation.

The only further process which the indigo undergoes, is that of drying, which sometimes is effected solely by dripping; at other times it is subjected to a pressure, by which the water is squeezed out. It is exposed to a fine current of air, but shaded from the light of the sun.

Indigo differs greatly in its excellence, as well as in its accidental properties. Some specimens of it have much less specific gravity than others, and the lightest is the purest. Some of it will even float in water. If the air is excluded while it is in any degree moist, it undergoes a chemical change, by which white specks are formed in its substance. When too much lime has been used in precipitation, it subsides mixed with the indigo, and throws down other adulterating matters. Indigo differs greatly in colour. Of the Guatimala indigo, the most esteemed sort which comes from America, there are three varieties; one called flore, has a fine blue colour; a second, called sobre saliente, is violet; and the third, called cortic-color, is copper coloured. When the first sells at 9s. per lb., the second is 7s. and the third 6s. 6d. Of the East Indian indigo, the Javanese was formerly preferred to all others; but the manufacture is now cultivated to a considerable extent in the British possessions, and an article is produced which is often superior even to that of Guatimala.

The comparative value of indigo may be ascertained by dissolving equal portions of different specimens in sulphuric acid, and afterwards comparing the quantities of oxymuriatic acid requisite to destroy the colour of each. Dr. Bancroft proposes to compare merely the depth of the colours, which the same proportion of each communicate to water—a test which must be less accurate. M. Chevreul analysed the best Guatimala indigo, and found that it contained other ingredients besides the true colouring matter. He obtained from it, by hot water, an oxygenated base of indigo, with a green matter united to gum, some ammonia, and a little yellow extractive, amounting in all to 12 parts in 100. From the remaining 88 he obtained, by digesting with alcohol, 30 parts, consisting of a green matter, a reddish resin, and a little indigo. By digesting the residue with muriatic acid, he obtained 2 parts of red resin, 2 of carbonate of iron, 2 of red oxide of iron combined with aluminoous earth, and there remained 3 parts of silex, and 45 of pure indigo. This last alone gave out the beautiful purple smoke on burning, which characterises indigo, and which is the substance itself in a state of sublimation. When thus purified, it is of a purple colour, a circumstance which is also observed to take place with Prussian blue, when most condensed. Bergouau obtained 47 parts of pure indigo from the article of commerce, which, when distilled, yielded 2 parts of carbonic acid, 8 of an alkaline liquor, 9 of empyreumatic oil, 23 of a charcoal, containing 2 parts of oxide of iron, and 2 of silex.

Some have attributed the blue colour of the indigo to iron, but this is improbable. Chapital ascribes it to charcoal; but the mode of combination in which the colouring matter exists, is so peculiar, that we ought not to ascribe it exclusively to one principle. One thing in it remarkable, is, that the compound base shews a stronger affinity among its components parts, than that which takes place between it and oxygen, as the base may be obtained in a limpid state, in which it requires only the addition of oxygen to impart to it the colouring property. It is by being deprived of a part of its oxygen that it is rendered soluble. This was formerly done by mixing it with woof which had been fermented. A boiling decoction of wool, madder, and broom was at first poured on the woof, and allowed to stand in a proper temperature, till blue veins were formed on its surface. Quicklime, and the indigo in powder, are then added, and the fermentation continued. The liquor becomes green and fit for dyeing. This process is employed in dyeing woollen stuffs; but the proportion of lime requires to be carefully adjusted. When in excess, it imparts to it a brown colour. For the same purpose of disengaging the oxygen, or a part of it, urine is employed, also metallic salts, such as green sulphate of iron, in which the metal is at an inferior degree of oxidation: arsenic and oxide of tin are used for the same purpose, or metallic tin assisted by the muriatic or other acids. The substance chiefly employed as a solvent of indigo, without depriving it of its oxygen, or imparting any temporary change of colour, is sulphuric acid. These processes form part of the art of Dyeing, and to that article we refer for the details. See Dr. Bancroft’s Researches concerning the Philosophy of Permanent Colours. Chemistry, vol. vi. p. 112; and Indira. p. 85. (H. D.)

INDRE, the name of one of the central departments of France, which derives its name from the river Indre, with which it is traversed. It is bounded on the north by the department of the Loire and Cher, on the east by that of the Cher, on the south by the departments of Creuse and Upper Vienne, and on the west by those of Vienne, and the Indre and Loire. This department is about 56 miles from north to south, and 45 from east to west. It contains 362 square leagues. The western part of the department abounds in rocks, pools, and woods; but the part on the right hand of the Indre contains fine fields and vineyards, which afford grain and excellent pasturage. There are iron mines, marble quarries, and mineral waters in the department. The contribution amounted to 1,652,606 francs, and the population to 207,911 inhabitants. Chateaureulx is the principal town. See France, vol. ix. p. 675.

INDRE AND LOIRE, is the name of one of the western departments of France, which derives its name
from the union of the two rivers, the Indre and the Loire. It is bounded on the north by the department of the Sartre, on the east by the department of the Loire and Cher, and the Indre; on the south and south-west by the department of the Vienne, and on the west and north-west by the department of the Mayenne and Loire. It extends about 50 miles from north to south, and 45 from east to west, and contains about 325 square leagues. This department has been called the garden of France, on account of its great fertility. The peninsula formed by the Indre, the Loire, and the Vienne, is extremely fertile. The district between the Loire and the Cher is light and sandy, though productive. Rye, barley, millet, wine, fruits, and pastureage, are the principal productions, and it contains also iron mines, and mineral springs. The annual contributions were 2,868,779 francs, and the population 278,758. Tours is the capital of the department. See France, vol. ix. p. 675.

INDUCTION. See Logic.

INDUS, a celebrated river in India, known to the ancients by the name of Sindus, or Sinthus; is called the Sindhu, or Sindhus, in the Sanscrit; and Anb Sin- de, or the water of Sinde, by the Persians. Its source has never been explored, and still remains a subject of conjecture. The natives of Hindostan assign to it a very remote origin in the mountains, four or five days journey to the north-west of Yarchand; which would place it near the city of Cashgar, in Chinese Tartary, about 44° north latitude, and 70° east longitude. Hence they describe it as taking a southerly direction, and approaching within two days journey of Lahdock; then turning west, as far as Saighur, (probably the same as Shekerdon,) and afterwards proceeding in a direct course to the south. Mr. Colebrook supposes that it may originate on the western side of the great Himalaya range of mountains, and thence take a sweep to the north. It enters Hindostan about 33° 15′ north latitude, where it is joined by the Attock or Cabul river, after which it is no longer fordable, and is about three-fourths of a mile in breadth in the month of July. As it proceeds along the frontiers of Afghanistan, it receives all the principal streams of that region; and, from Calabau towards northwards, it is a clear stream, rather deep than broad, flowing between two ridges of rocks, and yielding from its banks abundance of salt and alum. In the province of Mooltan, it receives all the rivers of Lahore or the Punjab, and increases considerably both in depth and breadth; but is not considered as one of the five rivers, which give the name to the Punjab, being rather the trunk or stock into which the Cabul and Lahore waters flow. About 170 miles from the sea, it divides into two branches, of which the westmost is the largest. This branch, after proceeding about 50 miles to the south-west, divides again into two parts; and, as it approaches the sea, is subdivided into several other branches or creeks, like the Sunderbunds or Delta of the Ganges, of which the largest is the Ritchel. At the months of these different branches, the bore or sudden influx of the tide is extremely high and hazardous; but it is a remarkable circumstance that the tides are not visible up the river at a greater distance than 60 or 65 miles from the sea. From Attock to Mooltan, it is called Attock, or formerly Nilab; and, farther down, it is named Seor or Shoor, till it separates at Tatta, (supposed to be the ancient Pattala), when its largest branch is denominated Mekran. Its whole course, including its windings, and supposing it to originate to the north-west of Cashgar, is estimated at 1700 miles. From Attock to the Delta, its breadth is generally about a mile, and its depth varying from two to five fathoms. It is navigable for vessels of 200 tons burden, from the Gulf of Cutch to Lahore—a distance of 760 geographical miles. From Attock to the sea, a distance of nearly 900 miles, it runs south by west, with fewer windings than any other river in India; and forms, through the whole of that extent, a distinct barrier to Hindostan, which has never yet been passed by any of the invading armies. Its two principal months are those which enter the sea at the village of Ritchel, and at Jiget Point in the Gulf of Cutch; but the number and positions of its several outlets have been very imperfectly ascertained. The Delta of the Indus is about 150 British miles in length along the coast, and 115 in depth from the separation of the superior branches to the most prominent point of the sea coast. The lower part of this Delta is intersected by creeks and rivers in almost every direction, but is altogether destitute of trees; and, except a few of the drier spots, which are covered with brushwood, it is a mere desert of arid sand, noisome swamps, and muddy lakes. The upper part is well cultivated, and forms a part of rice, which is mentioned by Abul Fazal as forming, with fish, the principal food of the inhabitants of these districts. A great portion of the Delta, especially the nearest to the sea, is set apart for the rearing of camels, which feed upon the tender parts of the brushwood. See Rem's Memoir of a Map of Hindostan; Foster's Journey from Bengal to England; Hamilton's East India Gazetteer; and Tennant's Indian Recreations.

INFANTICIDE. The solicitude almost universally observed for the preservation of human life, has been subject to some remarkable exceptions in different ages, and in various parts of the world. Not only has the ordinary course of nature been interrupted in restricting the intercourse of the sexes by positive ordinances, civil or ecclesiastical, but the latent embryo has been destroyed in its progress to maturity, and the infant consigned to death at the moment of beholding the light of day.

Parental affection seems so deeply rooted in mankind, by a wise provision for the protection of the offspring, that, without actual evidence, it would be difficult to credit the extent to which infanticide has extended.

It has been affirmed by some learned authors, that the sole purpose of nature in preserving the animal kingdom is the reproduction of the species. Yet mankind, as if to disappoint her object, condemn themselves to celibacy, sometimes by vows of such a nature, that their infringement would be attended with the forfeiture of life. Nay, there are repeated instances of married persons having withdrawn from each other's society from similar motives. Mandelslo relates, that, in the Island of Formosa, the women have no children until they are 35 or 36, "from the impression they receive from their priestesses, that it were a great sin and shame for them to bear children before that age." Therefore, should they become pregnant previously, abortion is procured by violent means, and by the assistance of the priestesses themselves. The laws of Tunkin are so severe against having illicit offspring, that the same practice prevails; and it is thence so frequent, that there are women whose profession it is to facilitate and obtain abortion. It is said, by Krascheninikow, that there are females in Kamtschatka who use herbs and conjurations to prevent conception, and that they procure abortions by means of
infanticide

Destitute by procuring abortion.

poisonous medicines, wherein they are assisted by skilful old women. McKenzie, the late traveller across the North American Continent, affirms that the women of the Kistineaux frequently procure abortion to avoid the distress consequent on taking care of, and maintaining, their children. The Eskimaua, inhabiting the shores of Hudson's Bay, according to Ellis, constrain their wives to obtain frequent abortions for the same cause, by means of an herb common in that country; and an older author, Denys, says, that if a woman of North America became pregnant while suckling her child, she obtained abortion; alleging, that nursing one at a time was enough. Other examples might be given; for procuring abortion is common over the world, and must to a certain extent prevail where misfortune or disgrace attend the birth of the offspring.

There is too great reason for considering these motives as the cause of infanticide where the child is actually born. The instances of it are innumerable, though arising also from different causes. Among the inhabitants of the Kurile islands, it is customary to destroy one child of every pair. The Natives of the neighbourhood of Berbice, are said to do so, from believing that the birth of two children proves the infidelity of the mother. Kolben informs us that the ugliest of the Hottentot female wins is put to death, under the pretext that a mother cannot suckle two females at once. At least one of twins was wont to be destroyed with the Kantschadale; and in New Holland, the weakest and lightest is quickly suffocated by the mother.

As there is greater difficulty experienced in supporting feeble and sickly children, or those labouring under prominent personal imperfections, so the parents have had less hesitation in breading them of existence. Diadorus relates, that all deformed children in Taprobana, which we suppose is Ceylon, were put to death. Quintus Curtius says the same of those in the kingdom of Sophitus. promising children were reared in Sparta: the others were destroyed; nor could parents spare those whom they chose; as they were submitted to the examination of certain persons, and if weak or deformed, were thrown into a cavern. Gemelli Careri was told in Paragon, one of the Philippine islands, that children born with imperfections, which would apparently disable them from working, were put alive into a hollow cane, and buried. These cruel expedients must be viewed as the result of necessity rather than of choice; because in countries where each has to depend on his own personal exertion for a precarious subsistence, there is no room to provide for the helpless. It has even been seen, that, by a barbarous custom, originating from a similar source, when a man perished, his widow and orphans were put to death; not from the desire of shedding blood, but because the survivors had no means of supporting them. In Greenland, when the mother of an infant at the breast died, the child was buried along with her, if the father and relations could not find a nurse. At the present day, it seems an invariable practice of the savages of New Holland, to inter the sucking infant in the same grave with its departed mother; nay, the father is the first to heap the earth over the bodies of both. No concern is testified by the relatives for its fate. They seem satisfied that this is what ought to be done; for their own helpless condition deprives them of the means of providing for a being still more helpless than that one.

Causes of infanticide.

The sources of infanticide may, in general, be traced to necessity, superstition, the love of pleasure, and shame. Mothers in Japan, it is affirmed, do not scruple to suffocate children at the breast, on finding themselves too poor to bring them up. Infanticide is said to be common in China exclusively from that cause. The women of the Kistineaux, whom we have already named, frequently put their daughters to death to spare them the miseries attached to a life of continual pain and labour, which is their own condition. According to Gumilla, the South American women on the river Orinooko, are so keenly alive to the unfortunate condition of their sex, that, to spare their daughters from it, they cut the navel string too close, that they may perish. A missionary having reproached a woman with the cruelty of this practice, "Would to God," she replied, "that my mother, when she brought me forth, had shewn as much compassion and regard for me as to have preserved me from the pain I have endured and must endure until the end of my days. Had she buried me alive when I was born, I should not have felt death, and it would have saved me from all I am indolently subject to, as well as labours more cruel than death is terrifying. Would to God, father, I repeat, would to God that she gave me life had she shewn her affection by depriving me of it at my birth: my heart would have had less to suffer, and my eyes less to weep!"

In most countries, it is the female offspring which is doomed to destruction, while the males are spared: thus, if the twins of the New Hollander be of a different sex, it is the daughter alone that perishes. Dobrizhoffer relates, that he has known mothers among the Abiponians, a South American tribe, who destroyed the whole offspring as soon as they were born; but others more commonly spared the males than the females. The ancient Arabsians, especially those of the tribes Koreish and Ken-dab, were accustomed to bury their daughters, from the apprehension of inability to provide for them, as also, it is said, from the grief which would be felt on their becoming captives, or from their immoral conduct. But most probably the first was the leading cause, which, as well as the fact itself, is proved by various passages in the Koran: "Verify the Lord will enlarge the store of whom he pleaseth, and will be sparing unto whom he pleaseth: will not your children, for fear of being brought to want; we will provide for them and for you; verify the killing of them is a great sin." By this, and other injunctions of Mahomet, the practice is supposed to have been abolished in Arabia. Probably it never was universal there. But it has been reserved for modern times to discover the existence of a numerous tribe which seems to have destroyed almost the whole female offspring without exception. As the British dominions extended to the north-west of the Indian peninsula, a certain race called Jarejahs, was found in the province of Guzerat, and the district of Cutch, where civilization had made considerable advances, and where the nature of the country removed all apprehensions of want. Here there are different gradations of rank, and the members of this tribe are far superior in point of refinement to those in savage life. The Jarejahs destroy all their daughters at the moment of their birth, just as the result of an ordinary custom, which excites no concern, and induces no reproach. But if the deed is not perpetrated immediately on birth, it becomes criminal: It is also done in obedience to the will of the father, who may direct the life of the infant to be spared. The birth of a son among these people is one of mirth and festivities, that of a daughter passes unnoticed. As Mahomet writes of the ancient Arabs, "and when any of them is told the news of the birth of a female, his face

Female infanticide in India.
Infanticide.  

Female infanticide in India.

becometh black, and he is deeply afflicted; he hideth himself from the people, because of the ill tidings which have been told him, considering within himself whether he shall keep it with disgrace, or bury it in the dust. On the birth of a daughter, it is said that the attendants of the mother repair to the oldest man in the house, who desires them to go to the father of the infant, and obey his orders. They do so, and he merely enjoins them to act as is customary, and so to inform the mother. On their return, she is told to proceed in conformity to their usage. It seems doubtful, however, whether all this ceremonial truly ensues, for ceremonies are generally obliterated in matters of frequent occurrence; but the death of the infant undoubtedly follows, and more commonly by the hands of the mother. Yet here there is much mystery preserved, somewhat similar, as we shall see, to the customs of that society which is instituted exclusively for the purpose of infanticide. The deed is committed in private, though not with the design of concealment, for neither shame nor punishment is its consequence. Ladies of rank, who may have slaves or servants, are said sometimes to charge them with this cruel office, but they are usually the perpetrators themselves. As to the mode of destruction, it is figuratively expressed by the Jarejahs that the infant is drowned in milk; but it rather appears, that when the mother is apprized of the paternal sentence, she puts opium on the nipple of her breast, which being absorbed along with the milk, speedily extinguishes life. When destroyed, the infant is put into a basket, and carried out for interment. The extent to which female infanticide is carried in Cutch and Guzerat is surprising, not fewer than 3000 females perish yearly in the former, and it is affirmed 20,000 in the latter. It will appear strange how the race can be preserved under such a system of depopulation; but natural children are not within its sphere; wives are obtained by the men from other tribes, and there are, besides, a few exceptions in parents sparing their daughters. No account of the origin of the custom can be given by the Jarejahs, who affirm that it subsisted among them for 5000 years. Fortunately for the natives of Guzerat, the British influence extended to that province, and the resident, Lieutenant-Colonel Walker, (who now resides on his property of Bowland in Selkirkshire,) conceived the possibility of abrogating a custom so revolting to humanity. He endeavoured, with admirable skill and perseverance, not only to divert the chief men of the country from this horrible practice, but to gain the support of the female part of the inhabitants in promoting his views. Many difficulties opposed his wise and benevolent exertions; but he had at last the felicity of seeing them crowned with complete success. The chiefs renounced a practice, which they defended as having been interwoven with the existence of their tribe for thousands of years; mothers soon brought their offspring, thus saved from premature destruction, to the arms of their preserver; and the very first lesson they were taught was to pronounce his name. It must certainly appear singular, that prejudices so deeply implanted, and passing, as it were, by inheritance, could be rooted out by the efforts of one individual, and thus admit a benefit of such magnitude being conferred on humanity. But when reflection is awakened to the welfare of our offspring, it is nature which begins to plead, and whose voice will surmount almost every obstacle.

Other instances may be given of that infanticide which is not restricted to females. Krascheninikow says, that there are some of the Kamtschadalie women so unnatural, as to destroy their children when born, or throw them alive to the dogs. The missionaries affirm, that the Bojcesmans, or Bushmen, an African tribe, whose history is little known, “take no great care of their children; that they kill them without remorse on various occasions, as when they are ill-shaped, or when they are in want of food. When the father of a child has forsaken its mother, or when obliged to fly from the Dutch boors, or from others, they will strangle them, another then, cast them away in the desert, or bury them alive.” Should there be no exaggeration here, the barbarity of these savages is greater than that of any other tribe whose name is preserved in history. But the missionaries even seem to assert, that a lion comes to their dwelling for the express purpose of devouring infants. “There are instances of parents throwing their tender offspring to the hungry lion, who stands roaring before their cavern, refusing to depart until some peace offering be made to him.” Mr. Barrow passes a strong censure on this sentence; but, when stripped of its apparent extravagance, it may be resolved into what a later missionary, Mr. Campbell, expresses with greater simplicity, “the Dutch boors affirm, that the Bushmen often throw their children to the lion to preserve themselves, which has greatly increased the desire of these animals after human flesh, especially the flesh of Bushmen, so much so, that were a lion to find a white man and a Bushman asleep together, he would take the Bushman and leave the white man.” The same author mentions, that the Bushmen are very kind to their own offspring. “They have many instances of those who have had children murdering them, if the father refused to provide for them.”

It is generally agreed that infanticide is universal in China, being either immediately committed by the hands of the parents, or resulting from exposure to the influence of the elements. The exposure of children was a privilege commonly sanctioned among the ancients; it was so prevalent, that Aelian celebrates the humanity of the Thebans, who decreed capital punishment against it: nevertheless, where the parents were in poverty, they might offer the child for a price to the magistrates, who, having brought it up, were entitled to sell it for a slave. Almost all the children exposed in China are females; and the number, though it be difficult to approximate the truth, is certainly very great. Mr. Barrow computes, from the most authentic data which may be deduced from the statement of the missionaries, that it is not less than 9000 in Pekin, the capital, and as many in the provinces. It is part of the duty of the police, to carry away in carts early every morning, those who may have been exposed during the night. No inquiries are made: many are dead, but some still survive, and all are conveyed to a pit without the walls, wherein they are thrown promiscuously. Here the Roman Catholic missionaries attend, selecting the most lively among the infants for future proselytes, and administering baptism to others before they are left to expire. The causes of exposure and infanticide are sought in the necessities of the parents, as with the ruder nations; for those least capable of providing for themselves are compelled to abandon their offspring. Infanticide is well known to be connived at by the Chinese government, and never the subject of punishment.

Instead of awaiting that period, however, when even Society for by exposure an infant may have the chance of surviving, we find the Arreys forming a mysterious society expressly for the purpose of destroying their whole offspring at the moment of birth. This society is peculiar to the islands in the South Pacific Ocean.
INFANTICIDE.

It consists of both sexes, and is chiefly composed on the one part of persons distinguished by valor or merit; whence some of the families of the chiefs are always of the number. The greatest trust and confidence are reposed in its members; and it appears that the females are principally of the highest rank. The whole enjoy great privileges, and are everywhere united by the ties of reciprocal friendship and hospitality; their clothes are of the finest materials; they feed on the choicest delicacies. They pass their time in the enjoyment of luxuries, and travel about in great companies from island to island, where nocturnal sports are held for their amusement, along with lascivious dances, to which no other spectators are admitted. They are considered a class separate from the other inhabitants, entitled to every distinction and gratification. Different gradations subsist among them, which are externally demonstrated by the mode of tattooing their bodies. By the fundamental laws of the Arreoyas, their whole offspring must be destroyed; and it is to be inferred that the murder is perpetrated in solitude, and immediately after birth. None must be present, or behold its commission, otherwise they would themselves be deemed participants in the crime, and liable to forfeit their lives. The ordinances of this society seem absolute and imperative; and although any member may withdraw, while the association subsists, the offspring must perish. A woman who does so, however, inures a reproachful name, signifying "the bearer of children." An instance is quoted of a chief who killed his first born child, but preserved the second, having ceased to be an Arreoy in the interval. Another chief married a sister of one of the kings of Otahiti, by whom he had eight children, and the whole, without exception, were destroyed; yet the parents afterwards adopted a nephew as their heir. The proceedings and peculiarities of this society are veiled in mystery; they have never been explained, and all that can be said on the subject, consists of mere gleanings from transient observation. It is not proved that the mother usually suffers much distress from the death of her infant; and so little criminality, in the opinion of the South Sea islanders, attaches to the deed, that women disclose, without scruple, the number they have killed. Examples occur of mothers whose feelings are awakened, resisting every importunity to murder their offspring. The ultimate object of this association always is infanticide: it is not known that any similar society exists, or has existed; for the words of Father Gobien, which have been referred to, are not sufficiently explicit to establish the reverse. He observes, that in the Ladrone Islands there were young people called Urrius, who never married, and lived together in a kind of community in unbridled debauchery. They carried a certain ornamented staff as a badge of distinction; and the Spaniards having attempted to destroy the public dwellings which they inhabited, some of the missionaries became the victims of their resentment. Independent of the infanticide of the Arreoyas, it seems a common practice among the South Sea islanders. Where an Otahitian chief has a child by a woman of the lower order, it is never suffered to live; and the like seems to take place reciprocally with the higher ranks of females. All their natural children must perish. No satisfactory conjectures can be offered concerning the origin and purpose of this mysterious society. Its source has been sought in the provision of some wise lawgiver to check superabundant population; but who has ever heard of mankind dwelling in territories, frequently fertile, destroy one another's lives to obtain a greater portion of subsistence? Others have ascribed its contrivance to the pursuit of pleasure, which, without such restraints, might be more freely courted; and if we may reason from analogy, the reasons actuating the Abiponian women will support this opinion. During three years that children are suckled among that tribe, no conjugal intercourse subsists between the spouses; the husband sometimes takes another wife in the interval; and to obviate these alienations, or even repudiation itself, the mother destroys her progeny.

But we shall find a more powerful motive for infanticide than all the rest, in that unbounded ascendancy which superstition sometimes gains over the human mind. The practice of the moderns, however, is not so explicit in this respect as what we may collect from antiquity. It is said that the Kamtschadalas destroy their children if born during storms, though the necessity of doing so may be averted by conjurations. The indigenous inhabitants of Madagascar and Ceylon are likewise accused of infanticide, should the epoch of the birth of a child be declared unfortunate by their priests and astrologers. Certain periods of time, as the months of March and April, the last week of every month, together with every Thursday and Friday, are judged ominous. The child born at these times, will either be animated by evil propensities, or occasion numberless disasters, from which exemption is purchased by the sacrifice of its life. Mankind have been prone to embrace their hands in each other's blood, to propitiate or appease their sanguinary deities. But of all offerings, children were deemed the most acceptable, being a sacrifice of what was the most precious to parents. The Moabites offered up their children for propitiation in desperate enterprises. Thus, "when the King of Moab saw that the battle was too sore for him, he took with him 700 men that drew swords, to break through, even unto the King of Edom: but they could not. Then he took his eldest son, that should have reigned in his stead, and offered him for a burnt offering upon the wall." 2 Kings, iii. 27. Again, it is said that Balak, King of Moab, consulting Balaam, the son of Beor of Mesopotamia, and calling on him to come and curse his enemies, exclaimed, "Wherewith shall I come before the Lord, and bow myself before the high God? Shall I come before him with burnt offerings, with calves of a year old? Will the Lord be pleased with thousands of rams, or with ten thousand rivers of oil? Shall I give my firstborn for my transgressions, the fruit of my body for the sin of my soul?" Micah vi. 7. We read that Hamilcar, on receiving similar intelligence, attended with alarming circumstances, immediately seized on a boy, and offered him for a sacrifice to the deity Kronus: while, for an opposite reason, after Hannibal had gained the battles of Ticinus and Trebia, it was proposed in the senate to sacrifice his infant son. On occasion of an enemy being at the gates of Carthage, Diodorus relates, that 200 children, of the most distinguishable citizens, were offered up to the sanguinary deities to avert the danger. We read also, though with more uncertainty of the fact, that the Grecian soothsayers recommended the sacrifice of Iphigenia, the daughter of Agamemnon, to Diana. In descending to a more modern period of history, Hacoon, King of Norway, offered his son to Odin to obtain a victory over his enemy Harold; and Harold, the son of Guinild, sacrificed two of his children to his idols, to obtain a
tempest for dispersion of a hostile fleet. The modern Peruvians are said to have sacrificed their first-born to redeem their own life when in a state of sickness, as Aine, King of Sweden, in older times, sought to purchase a prolongation of his life with the blood of nine sons. It was with them as the Israelites, "Yea, they sacrificed their sons and their daughters unto devils; and shed innocent blood, even the blood of their sons and daughters, whom they sacrificed unto the idols of Canaan." Psalm cxi. 87. Thus can the powerful ascendency of superstition still the feelings of nature. Nay, the mother herself, who offered her child in sacrifice, never uttered a sigh, lest its efficacy might be impaired, and while the vital stream was flowing from a multitude of innocent victims, their screams were drowned by the noise of drums and trumpets sounding before the idol. "Tell me," exclaims Plutarch, "were the Typhons and the Giants to expel the gods, would they exact such horrid rites of me?"

Infanticide may therefore be traced to a feeling of shame on the part of the parent, which she has not fortitude to bear to necessities circumstances, to the pursuit of pleasure, and to the influence of superstition. We cannot affirm, however, that such are exclusive its sources; but it is probable that many others will be disclosed. INFinitive. See GrammAR.

INFIRMARY. A building provided by the public, or by charitable persons, and endowed with funds for the treatment of the diseases of the poor.

Infirmaries are among the most laudable of all charitable establishments, and do not fall under the same objections with some others. They do not, like the system of poor laws, encourage intolERENCE, carelessness, and improvident marriages; nor do they depress the minds of the individuals who obtain relief. Accidental injuries, and attacks of disease, are not, like the unavoidable infirmities of old age, evils with which all must lay their account, and against which a manly spirit calls on every person to make a definite provision. It is undoubtedly to be commended, when the labouring classes provide against every casualty. But evils of this description often intervene unexpectedly, when want of time, and other pressing claims, have rendered such a degree of successful providence impracticable; and the evils, when they come, are in their nature overwhelming. It is a noble feature of human sympathy, to find society so constructed, that institutions exist on a scale sufficiently large to afford a ready attention to every emergency of this sort that occurs in the average course of events.

It is to the spirit of Christianity that we are indebted for them. They seem to have had their origin about the time of the Emperor Justinian. It has become a question among some of the moderns, who have seen the impiecations attending our existing institutions, How was the want of them supplied among the ancients? It seems to have been expected that, from their practices, some hints might be obtained by which our plans of charity might be improved. But it ought to be recollected, that the mass of misery which exists in such an imperfect state of society must pass unknown. An immediate neighbour may become acquainted with a scene of distress, and may exert himself to relieve it; but, where no general encouragement is held out to make known cases of this kind to those who are ready to relieve them on such a scale as can be depended on, they remain neglected. The persons whom our infirmaries relieve, would, among the ancient Greeks and Romans, have languished and died with disease and hunger. Pity impelled numerous individuals in the Christian world to appropriate a part of their funds, either during life, or after their death, to religious and charitable purposes. By institutions proceeding from this origin, an immunity of benefit was conferred on the sick poor. But these became liable to abuses which had not been foreseen, and ages of experience were required for the formation of a correct policy. The funds devoted to charitable purposes, being unalienable, tended perpetually to accumulate, and gradually to absorb every other kind of property, and the monastic institutions with which they were connected, became the abodes of idleness, and were contaminated with extravagance and debauchery. The Reformation, together with an internal correction of abuses in the church of Rome, placed these, among many other establishments, on a better foundation. The greater part of our infirmaries are of an origin much posterior to the Reformation; and some of those of Catholic countries are less dependent on monasteries than formerly. It would be a matter of too tedious detail to enter on their individual history. In all the European capitals, and most of the other large towns, infirmaries are established. In London, there are seven general institutions of that sort, besides others more numerous, devoted to particular branches of the same benevolent object. Almost every large town in England, and several in Scotland, have one. These have been gradually improved, and the principles on which they are conducted have several leading features in common, though not always executed in the same manner. We hope our readers will be gratified, as well as instructed, by an account of some of the difficulties attending such institutions, and the manner in which they are surmounted. It will be found that it is not enough that the spirit of liberality should be sufficiently ample, to commence and endow them; and that much invention and sound judgment, together with persevering labour, are required on the part of those who conduct them.

In the first place, it has been found, that the crowd of many patients under one roof had the effect of exasperating several diseases, and of generating others, such as the hospital fever, and the hospital gangrene, which derived their names from these charitable institutions. It was found that the mortality thus occasioned was beyond all comparison greater than under all the disadvantages of domestic treatment. The Hotel Dieu of Paris, previously to its reformation, was the grave of the sick poor of that metropolis. Hence a general outcry was raised against infirmaries. It seemed dangerous to go near them; and the conclusion at one time appeared plausible, that they ought to be abolished. This, however, has not been found necessary.
The influence of contaminations of the atmosphere has been most accurately ascertained. It is now found that no disadvantage arises from a plurality of patients being within one building. All the reformation necessary was to avoid excessive crowding, and to resign the vain boast of the great numbers of patients contained in these places. The beds of infirmaries are now placed at proper distances. The wards are regularly ventilated. Frequent whitewashing of the walls, and cleaning of the floors are practised; and, in consequence of these observances, all the former evils have disappeared. It has been found that even contagious fevers may be safely treated under the same roof with promiscuous diseases, provided they are placed in separate wards to the ventilation of which due care is devoted. This object, however, has more recently been prosecuted by the erection of separate establishments, which we shall consider in the sequel.

Surgical cases. Serious surgical cases, such as injuries of the cranium, compound fractures of the limbs, and gun-shot wounds, when a plurality of them are brought together, have a tendency to generate an obstinacy in the healing process, and require still more care than in guarding against febrile contagion. This has been experienced in military hospitals, in the spread of the hospital sore. When it occurs, the dispersion of the patients is the most effectual method of stopping it.

Ventilation and cleanliness. Infirmaries are so constructed as to admit of thorough ventilation; the windows are made to open both from above and from below; in the former way, that fresh air may be admitted without a hurtful cold draught, and, in the latter, that the heavy polluted air, which is apt to rest in the inferior part of the wards, may be more effectually dislodged, by seasonably opening the inferior sash. The practice of collecting urine for the manufacturers, to which the servants of infirmaries were formerly tempted by money, is now discontinued. The bedsteads are of iron, a material to which contagious and other animal effluvia are less apt to adhere than to wood. The bed-clothes are more frequently washed; and, when it is convenient, they are regularly aired. For this last purpose, there is probably room for further improvement. We have sometimes contemplated a plan of having the beds of those patients who sit up through the day, so contrived, that, with little labour, they might be elevated by some simple machinery, by the windows, to the roof of the building, and brought in again at pleasure. Flock and feather beds are not used. The preference is given to straw, chaff, and other materials, which, from their low value, admit of frequent renewal. In cases in which articles are used which cannot be frequently renewed, they are exposed not only to frequent ventilation, but to purification by water.

Disturbances of patients prevented. There are other circumstances apt to occur in infirmaries, unfavourable to the recovery of the patients. They may be exposed to the sight of neighbouring patients in the agonies of death. This is remedied by having curtains or screens for the different beds; an arrangement which gives them the advantage of a more comfortable appearance, and more individual privacy. They are not employed in every infirmary, partly on account of the expense, and partly from the obstruction which they give to ventilation; but they ought always to be at hand, and rods to which they can be fixed should accompany each bed. The sight of epileptics, the unpleasant noise which they make in their fits, and the shocking spectacle, and stunning noise, of patients under insanity, are obviated by providing separate wards to which these may be sent, and also such patients, occasionally, as might annoy their neighbours by the piercing cries which under pain or delirium they emit. In some infirmaries, for example that of Glasgow, every ward has three single lettered rooms or tents, a method most admirably adapted to these purposes; as a patient may be instantly moved to one of them, without formality or trouble.

For the convenience of the surgeon, it has in some places been common to perform surgical operations at the bed-side, in sight of the other patients of the ward. This, which could not fail often to shock their feelings, is avoided by the easy regulation of having a separate theatre allotted for all surgical operations. Accordingly, no such practice exists in the British hospitals.

Some disadvantages have arisen from negligence on the part of the different servants and officers connected with these institutions. To obviate these is a difficult task, and requires the utmost vigilance. It is equally requisite to see that no abuses are committed by any of the patients themselves, to the detriment of others. A system of inspection is for these purposes evidently necessary. Monthly or weekly inspections are therefore practised. The nurses are examined apart from the patients about the conduct of the latter, and they, in their turn, about their satisfaction with the nurses. The medical gentlemen who reside in the house are under the direction of the attending physicians and surgeons; and these, notwithstanding the respectability of their station, and those principles of honour by which they are supposed to be actuated, are not placed above inspection and admonition. Though a rude and frequent interference on the part of persons who are not adequate judges of medical duties is avoided, the inquiries of the house visitors have it for a part of their object, to ascertain how the patients are satisfied with them. Opportunities are thus afforded for friendly and instructive explanations. The medical gentlemen derive gratification from the interest which others take in their duties; and, where all wish to do their duty, and possess that degree of patience which is necessary to every public character, a good understanding is cultivated. On occasions of a different kind, flagrant errors and abuses have been fully exposed, and the means have thus been afforded of putting an end to them. Different infirmaries enjoy different advantages for this species of vigilance, which often depend on the manner in which they are constituted. Where the number of managers is small, they have the best chance of maintaining harmony, and of understanding their duty. But they are apt to become remiss; and, from a false delicacy, to overlook the omissions of another, and of the principal officers. The duty of visiting the house is also apt to become too burdensome, when the turn to each comes frequently round. Where the number of managers is large, amounting, as in some instances, to hundreds, many of them are unacquainted with the nature of the institution, and either go through the forms of duty in their turn without intelligence or care, or mar the business of the charity, by encouraging frequent and vexatious complaints. It is pleasing, however, to find, that these ends are in general so effectually and agreeably obtained.

Infirmaries are liable to a variety of petty abuses, petty abuses which have a tendency to accumulate in their amount, and watch and thus generate much evil. One of these, is the practice of nurses taking money from the patients. This is not always easily prevented, as the latter feel a debt of personal gratitude; and it might appear hard to deprive
In infirmaries, the liberty of showing it, and the nurse of the opportunity of receiving a slender reward for superior attention. But it is necessary to suppress such a practice, otherwise it infallibly leads to a system of exactation which amounts to a robbery of the poor. The only way in which such practices could be at all tolerated, would be by prohibiting them while the patients are in the house, and conniving at expressions of their gratitude, which are made after the lapse of some days or weeks. Even this would not be safe, nor probably any thing short of a positive suppression of such perquisites, especially when we consider that the same patients may be liable to return.

A system of inspection and explanation does not merely secure the conducting of the charities on correct principles, but produces a most beneficial effect, by satisfying the minds of all concerned. Hence each patient is required to read an enumeration of the advantages of attendance which he may expect, and a statement of the behaviour required of him. A table of his diet is also shewn to him. This is a subject on which abuses might creep in. It is also one, on which hurtful mistakes, and unjust complaints, are liable to arise. Persons from a distant place, differing in its customs from that in which they are admitted into an infirmary, are sometimes apt to find fault with the provisions, and their complaints will always be more or less soothed, when they are informed of the usages of the country. Poor persons from the south of England find fault with the colour of their bread in the northern hospitals, though fully as wholesome as their own. When the reason of the difference is pointed out, they may despise the customs of the place, but they cease to harbour the idea that they are defrauded of a right. In all public matters, systematic explanations compose the public mind, and produce a charming alteration on the moral aspect of society. It is better to cure jealousy by intelligence, than to suppress it by inculcating blind confidence.

Public charities are in some particulars apt to operate unfavourably on the moral feelings of those who are relieved. We have already stated the encouragement of indulgence as one of these, but one from which infirmaries are exempt. Another is a tendency to generate a depressing sense of dependence. Some attempt to remove this, by teaching the patients to look on such relief as a right rather than a favour,—a notion, which is considered as keeping erect the dignity of an independent mind. Some delicate distinctions, however, are here requisite for moral practice. Such relief must not be considered as a right of the same indefeasible kind, as those advantages that are obtained by a man at his own expense. The duties of charity are of such a nature, that their limits and appropriate occasions do not admit of being easily defined. They require much reflection and care in the performance, and the neglect of them is more excusable than an act of common injustice. This ought never to be forgotten, otherwise the person who receives charity cherishes unreasonable expectations. While the poor man applies for the relief provided by public institutions with a mind sensible of his claims, he must be taught to recognize the spirit of active benevolence in others, without which his wants could not be supplied. If he does not, his independence degenerates into pertness, ingratitude, and clamour. When matters are thus cautiously and modestly conducted, the moral feelings both of rich and poor are improved. The rich find that they are relieving persons in whose situation they may afterwards, by the reverses of human affairs, be placed; thus their deeds of charity remind them of the lot of mortality. Humbling instances of such reverses frequently fall under the observation of those who visit infirmaries. They are also made to reflect, that no man is absolutely independent. The rich depend on the poor as well as the poor on the rich, and they feel that their deeds of charity are only acts of justice, though they derive in the eyes of others a merit from being voluntarily and cheerfully performed.

For the sake of preventing any unnecessary mortification that might occur, as well as dispensing bounty in a more equitable manner, some descriptions of patients are required to make a payment in the name of board. In some cases of this kind, a difference has been made in the diet. This is perhaps injudicious. The diet of all ought to be wholesome, and the only differences allowed should be those that are rendered proper by the state of the complaint. Any other distinction has a tendency to mortify the more helpless of the patients, unless they are completely separated.

Moral disadvantages are apt to arise from the mixture of estates. It is not possible to prevent these disadvantages. The virtuous are shocked, and made unhappy by the profusion of the vicious, and may afterwards be disposed to dissipate others from entering such houses; while the young, whose habits are not yet confirmed, are in danger of being corrupted by bad company. These evils are most apt to appear, where venereal patients are accommodated promiscuously with others. Accordingly this has been in a great measure corrected, by assigning to such persons distinct wards, and prohibiting all intercourse between them and others, or erecting separate institutions for their accommodation; such as that highly beneficent charity, the Lock Hospital in London, which holds forth to the diseased children of vice, both medicine and the sedulously employed means of reformation. Want of correctness is in other instances kept down by a system of domestic superintendence. A person of respectable character and manners, capable of exercising due authority, is selected for a matron, or house governor. This is particularly necessary, and sometimes requires great delicacy, when any of the resident medical officers are pupils, and young men addicted to pleasure, who require control for the prevention of abuses.

These charities are occasionally liable to be perverted by the persons who apply for relief. They are sometimes abused by daring impostors, who apply under the guise of distress so artfully assumed as to escape detection. This is not unfrequently done, for the mere purpose of obtaining temporary support. Hence the necessity of the utmost circumspection in examining the symptoms of the patient, and, where these are ambiguous, practising a well-directed policy for subjecting them to a full prosecution. Suspicions on this head authorize a practitioner to abridge for a day or two the comforts of such individuals,—a measure to which a sick man will submit, as intended for his recovery, while a conscious impostor will make his escape as soon as possible.

The strictest regulations are always practised for preventing the patients or their friends from bringing into an infirmary any provisions or articles of comfort, except such as are submitted to inspection, and for totally prohibiting the introduction of spirituous liquors. Habits of sobriety, thoughtfulness, and religion, also receive the usual encouragements, by the appointment of spiritual overseers, and the regular maintenance of religious worship.
The difficulty of managing all these complicated concerns, and the great labour which is, in most instances, bestowed on them, ought to be duly appreciated before any complaints are uttered against the imperfections of infirmaries. Nothing is more hurtful to society than the censorious spirit which conceives itself authorised to muller and frown on every occasion on which a colour appears, on a superficial glance, for pronouncing the words injustice, partiality, negligence, or others still more indignant. This spirit of complaint is fostered only to the persons who do not bestir themselves for active good. Those who are experienced in such affairs, are sensible of the difficulty both of executing justice and humanity; and, while they do not withhold their strictures on such imperfections as appear, bring them forward in the true spirit of social benignity, and thus contribute to improvement, without generating displeasure.

In many respects, infirmaries create additional comforts, and cherish additional virtues among those who fall under their protection. It is not unfrequently happens, that by bringing individuals into the notice of the friends of humanity, they have proved the means of accomplishing the moral reformation of the vicious, and on other occasions, providing encouragement to neglected genius, or unsuccessful industry. Employments are contrived for those patients who are able to work a little. They sometimes assist in the lighter domestic labours. A common occupation among them is that of preparing surgeon's lint from old linen. They thus acquire useful dexterities, which may afterwards promote their domestic comfort, and enable them to administer assistance to their neighbours in private life.

One article of comfort and of cure is provided in infirmaries, which is a powerful remedy in many cases of disease, yet, from the trouble of providing it, is too frequently postponed in private life, and is inconvenient even for persons in decent circumstances, viz. the cold and warm bath, especially the latter. Being always ready in an infirmary, it is exhibited at those times which are most suitable to the patient, or at such regular periods of the day, that the due preparation of the patient for it is always well timed. Thus it is not rendered abortive by the intervening of sleep, or of a change of symptoms.

While the more humble members of the community receive direct relief from infirmaries, these institutions prove beneficial to society at large, by the singular advantages which they present for the improvement of medical knowledge. Within a small compass, much more practice can be seen by a medical pupil, than by going round among the dwelling-houses of patients. Thus a larger portion of his time may be devoted to reading and other studies. With all the trouble and time he could expend, it would be impossible for him to see the same variety in private practice as at an infirmary. He not only sees those who are under the care of the physician or surgeon whom he follows: every extraordinary case within the walls becomes quickly talked of; and interesting surgical cases spontaneously strike the eye. The establishment of clinical lectures on the diseases of the patients, gives that complete theoretical knowledge of the student, which can only be obtained by a perfect combination of the theory with the practice, and of the detail of practical precepts, with the actual exemplification of the history of disease, and the changes produced by remedies. The interests of the patient are not sacrificed to the object of medical instruction. On the contrary, they materially promote one another. A practitioner who treats his patients in so public a manner, and lays himself under the pledge of explaining his reasons for every thing that he does, and for every omission, solicits new motives for the excitement of his diligence, and declines to screen his errors under those ambiguous pretexts for which private practice furnishes so ready opportunities.

The opening of the bodies of deceased patients is another advantage of the utmost importance in the conducting of infirmaries. This practice has often furnished an opulent fund of anatomical information. Dissections have been held up to the horror of the public, and have been mischievously represented as the ultimate object of the medical attendants of infirmaries. This is highly absurd. In infirmaries, as in private life, no inspections of bodies are made without the consent of the friends of the deceased, if he has any; and none are made different from those which a rational man would invite to be performed in his own family. When this is the case, no reason can exist that should prevent the performance of this sacred duty to the living. It is not for the personal gratification of the medical profession; it is for their instruction and usefulness in society that dissections are intended. The barbarous prejudices which existed against them among the ancients, retarded the progress of medicine, and kept it in a state of comparative inefficiency for many ages. Where such prejudices still prevail, let them be submitted to. Let medical knowledge continue obscure and stationary, if it cannot be improved without shocking the delicacy, or rousing the indignation of an ignorant age. But let those who are superior to this fastidiousness, use their endeavours to open the eyes of others, and, in a particular manner, by holding forth the enlightened examples of fathers, in the midst of their parental sorrow, examining with their own eyes and hands the bodies of the children whom they have lost. The illustrious Haller, while he commemorates the excellencies of a deceased son, adds, as a circumstance of course, that he gave his body to be dissected.

The seven general hospitals of the metropolis, viz. St. Bartholomew's, St. Thomas', Guy's, the London, the Westminster, St. George's, and the Middlesex, contain constantly about 1600 persons, and the annual number admitted is about 20,000.

We shall in this article take some notice of the succedaneous means which have served to complete the objects for which infirmaries are instituted.

It is for the relief of strangers and persons who have no permanent home that their utility is most highly conspicuous. In a large metropolis, numbers of labourers and artisans who have resorted thither for employment, occupy lodgings at weekly payments, which they cannot retain when sickness deprives them of their earnings. Strangers, also, who come from a distance for a temporary purpose, occasionally fall sick. Such are the poor Highlanders who annually migrate to the south of Scotland to assist in the harvest. Many of these obtain, in their casual sickness, a cure and an asylum at the Infirmary of Edinburgh, and are justly enumerated among the most interesting objects of public sympathy.

Yet it is not to strangers alone that these institutions are adapted. Many persons who are domesticated in the places where infirmaries are situated fall into sickness so overwhelming, that they require more care than their relations at home can bestow on them. Thus the family is not only deprived of the fruits of the industry of a member who has fallen sick, but is forced
to renounce part of its usual earnings in attending on this person. For these cases, infirmaries furnish a most
reasonable relief.

There are, however, cases of a different description, for which they are not suitable. Poor persons are of-
ten afflicted with slight complaints, which require med-
ical care to prevent them from becoming dangerous,
but to whom removal from their own houses is not
necessary, and would even prove injurious by prevent-
ing them from following their usual occupations. This
is frequently the case with the fathers and mothers of
families, whose domestic duties, as well as their other
exertions, are of great importance to society. For such
persons, dispensaries are formed, at which advice and
medicine are given to patients who attend on stated
days. Many of these are too poor to purchase medical
attendance, though able to make a scanty provision of
the necessaries of life. There are other patients whose
complaints are so tedious, that they could not be re-
tained in infirmaries without occupying the place of
others who are capable of receiving greater benefit.
There are some diseases for which infirmaries are posi-
tively improper, as they require the free air, the va-
ried scenery and exercise of the country, and may re-
cieve all the direction and all the medicine they need,
by occasionally repairing to a dispensary. The case is
similar with the aged poor, labouring under complaints
which admit of no radical cure.

Poor children, when they fall sick, require such a
degree of care as an infirmary does not afford, and their
parents usually object to the removal of them from their
own immediate superintendence. The necessities of this
description of patients are not yet in most places suffi-
ciently provided for. In Philadelphia, there is a societ-
y of benevolent females, who provide attendance in a
separate place for the children of the poor, even when
in health, in such a manner as to enable the mothers to
follow some species of industry. One of their expedients
for the abridgment of labour is, to have large cradles,
consisting of fourteen or sixteen subdivisions, each of
which admits a child, so that the attention of rocking
them can be paid by one, while the opportunities of in-
dustry are afforded to the mothers in the same house in
which their children are thus provided for. Similar apart-
ments might be assigned to the nursing and the medical
attendance of sick children. With regard to children
who are able to walk, the suggestions of Mr. Owen of
Lanark Mills, for consulting their comfort and good
behaviour, in a systematic and abridged manner, might
be advantageously applied to the formation of an insti-
tution for the cure of their diseases. All the institu-
tions now mentioned, will, like infirmaries, be liable,
in the first instance, to abuses; and the means of obvi-
ating these will gradually occur, in proportion as the
facts become known.

But many, even of adult patients, can neither be re-
lieved by infirmaries nor dispensaries. For this reason
schemes of more extended charity have been attempt-
ated, amounting to a regular gratuitous attendance of the
sick poor at their own houses. This would have ap-
ppeared at one time a plan of impracticable magnitude;
and, it must be confessed, that the enterprise of those
who undertook to execute it, is some times in danger
of being defeated by the inadequacy of the means which
can be provided, especially as many apply besides those
who are unable to provide for themselves. It is scarce-
ly possible in any place to find well-educated men, who
are supported by medical practice, in sufficient number
for so much labour; and the characters of those who
are connected with public charities will not allow them
to admit into their body any who are in this respect of a
decidedly inferior rank. By efforts of this nature, how-
ever, much good has undoubtedly been done. It still re-
ains a desideratum in medical charities to provide for
this object, consistently with the interests of the medical
attendants, and with the limitation of their duties to such
a scale of moderation as is compatible with cheerful
perseverance. After the funds are provided for fur-
ishing medicines for such institutions, it would be de-
sirable to provide salaries for the medical attendants,
not indeed adequate to their trouble, but serving as an
acknowledgement for their labour, and a partial pre-
serve against ultimate disgust in the execution of their
duty. This object would be well worthy of the se-
parate consideration of those prosperous individuals who
have it in contemplation to devote part of their riches
to charitable purposes, either in the form of donations
or bequests. It is most likely to be duly appreciated
by medical men who have acquired a fortune in the ex-
ercise of their profession, which they are disposed to
dedicate to public uses.

Some of the miseries accompanying the sickness for
which the poor are admitted into infirmaries, do not
come within the limits of these charities, and the relief
of them might be too burdensome, both for the atten-
tion and the funds which they would require. To these,
in some instances, the attention of the humane has been
directed, and the task of affording relief has been made
a separate object. An association was formed in Lon-
don in 1791, under the designation of the Samaritan So-
ciety, which attached itself to the London Hospital.
The singular utility of this laudable institution will be
best shown, by describing the views of its founders, as
exhibited in their first address to the public.

"Observations prove, that there is distress in hospitals
calling on humanity for consideration, that cannot be
brought within the provisions of those valuable institu-
tions.

I. Poor servants who have been obliged to quit their
places and go into hospitals, when dismissed cured, but
yet in a weak state, have frequently no friend to receive
them, or place wherein to lay their heads securely, till
they are reinstated in service.

II. Many young females, who, through distress, have
pawned or sold their clothing, when raised from the bed
of sickness, might be saved from ruin by proper assist-
ance.

III. Many within the walls of an hospital suffer the
greatest anguish, on account of their families at home
starving for want of the wages of their labour.

IV. Patients from remote parts of this kingdom,
when discharged from hospitals in a low, lamen, or in-
curable condition, frequently know not whither to
go, or what course to take, for avoiding worse evils
than have befallen them. And foreigners, under si-
milar circumstances, experience at least as great hard-
ships.

V. Many a languishing fellow creature, it is reason-
ablely supposed, might be saved by the opportune benefit
of fresh air for only a few days.

VI. The efficacy of the waters of Bath, where there
is an hospital for paupers, and of the sea, would proba-
bly preserve the lives of many, who are unable to de-
fray the little expense of a journey.

VII. In cases of mutilation, various services might be
rendered the sufferers towards gaining a livelihood.

VIII Patients are frequently without change of li-

Infallibility.
In the year 1793, a fever prevailed at Ashton-under-Lyne, which had been introduced by a patient from Manchester. On that occasion, a temporary institution, on the plan of a fever hospital, was formed at Ashton. This example animated the inhabitants of Manchester in the same cause. A plan was drawn up by Dr. Ferrier, containing his matured views of this subject, which he had attentively studied, and in which his zeal was deeply engaged. He pointed out the following fertile sources of fever among the poor: 1. Crowded lodging-houses; 2. Dwellings in cellar stories, which were damp and ill ventilated; and, 3. Cotton mills, which were kept close, warm, and crowded with people. The advantages he pointed out that would arise from a house of recovery, were, That air and convenience would be better consulted, proper nurses would be provided, and the spreading of the infection arrested. This measure was not at first readily acquired in all. It was conceived that the bringing of many infected persons under one roof would render that place a focus of contagion, which, in any populous quarter of the town, would be pregnant with danger. That prejudice, however, was in a short time removed. The point of doctrine which had been previously ascertained by the learned, was gradually impressed on others by experience,—that, when several persons are brought together in a well ventilated place, the effluvia emanating from each patient, instead of uniting with those from others, are dissipated by the qualities of the air, and by the means employed, whereas in ill ventilated private dwellings, the bad air, in which the people habitually live, cherishes and rapidly disseminates the contagion generated by a single case. In the proposed institution, the attention, and the whole conduct of the nurses, were to be placed under the best inspection. The access of unnecessary visitors was to be prohibited, and the visits of near relations prevented from becoming dangerous, by the enforcement of precautionary regulations in the mode of their intercourse with the sick. The clothes of the patients were to be stripped off as soon as they were brought into the house, put immediately into water, and afterwards well purified. The patients, while under treatment, were to wear clothes belonging to the institution, and dismissed in their own clothes, now in a clean state.

The patrons of this institution formed themselves into a Board of Health, which watched over the sources of infection, and encouraged the people to give them the earliest information of every appearance of fever. This board also actively propagated all that information requisite for promoting the general health, which was derived from the most enlightened sources.

The patrons of the Manchester Infirmary co-operated cordially with the Board of Health. Poor persons under fever had been formerly attended at their own houses by the physicians of that munificent charity; and a facility was thus afforded to the object in view, as these gentlemen, who were the best judges of the case, were to be authorised to send such patients to the House of Recovery. The means of conveyance were provided, all unnecessary delay was thus prevented, and orders were even given, when it was thought proper, to have the houses from which the patients were taken, white-washed and thoroughly purified.

In 1796, the House of Recovery of Manchester was on these principles first established at a time when fevers were extremely prevalent, and the numbers of febrile patients, attended by the physicians of the infirmary, were on the increase. In a few weeks, these began to be diminished, and the average number of fevers in that town has continued ever since to be much smaller than formerly. In the first year, they were reduced to 57, having been 226 in the year preceding; and, of these 57, several were brought from the suburbs, the fevers of which, in the preceding year, were not included in the 226.
One advantage of this institution was, that a spirit of co-operation on the part of the owners of cotton manufactories was excited, and the health of their work people became much more than formerly the subject of study.

It was also found that, of those who were seized with fever, a larger proportion now recovered, the medical practice being materially aided by the attendance of the comforts which this institution provided. "A clean bed, a quiet ward, an attentive nurse, and the frequent visits of the physician, were," as Dr. Ferriar observes, "so many medicines to a poor creature, who otherwise had been languishing in a damp cellar, or in a garret, exposed to the injuries of the weather, amidst the neglect and confusion of a wretched family, clamorous from hunger, or brutal from debauchery."

Some time intervened, after the first establishment of this institution, before it was placed on a scale sufficiently ample to comprehend all the cases that occurred in Manchester and its environs. But, after this was accomplished, the result was, according to Ferriar, that the medical faculty of the infirmry felt themselves complete masters of the disease. "Epidemic typhus," says this author, in the third volume of his Medical Histories and Reflections, published in 1810, "is now unknown to us, while it has been raging in some of the neighbouring towns."

Institutions of the same kind have been formed in London, Dublin, Liverpool, and several other populous towns. The principles on which these are founded are the same which have been enumerated, and the effects which have been produced by them correspond to those of the parent institution in Manchester.

In houses of recovery, one part is appropriated exclusively to men. In Manchester there is a ward for this purpose, under the same roof with those for typhus, but entering by a separate outer door, that the contagion of this disease, which is peculiarly difficult to be decomposed or dissipated, may be prevented from attacking the other patients or their attendants.

In London, a small-pox hospital has been long established, by which similar attention is given to patients under that disease, and the contagion is prevented from spreading, as it might otherwise do. The important object of inoculation has been comprehended by the same institution, first the variolous, and latterly the vaccine. See inoculation.

Among infirmaries limited to particular diseases may be mentioned, with applause, lunatic hospitals, (see insanity) lying-in hospitals, hospitals for phthisis, the Lock hospital in London; the hospital for diseases of the eye; and the cancer ward of the Middlesex hospital. The laws of these institutions are founded on the same principles as those of other infirmaries, with such variations in their application as are adapted to the nature of the particular objects to which they are directed. INFLAMMATION. See Medicine.

INFLEXION, or Diffraction of light, is a property of light, in consequence of which coloured fringes are produced, both without and within the shadow of bodies placed in a divergent beam of attenuated light. These fringes are not produced, as has always been supposed, by the action of the body near which the light passes, but arise from the constitution of light itself. In our article Optics, this curious subject will be treated at considerable length.

INFLUENZA. See Medicine.

INK, a liquor used for printing or writing. The colour chiefly wanted for these purposes is black; and the principal properties of good ink are deepness of colour, distinctness, and durableness. The vehicle employed for producing adhesion of the colour to the substance on which it is impressed, differs according to the instrument employed in forming the lines. It is chiefly on this account that printing ink and writing ink are of so different composition. We shall describe the modes of making the best inks of these two kinds, and then the different coloured inks, and the compositions known by the name of sympathetic inks, which last are, on the whole, more curious than useful.

Printing ink is a mixture of black carbonaceous matter and oil, and makes a near approach to black paint. It requires, however, some difference of mechanical properties. Paint is fixed by drawing a brush in lines along the substance to which it is applied. But printing ink is made to adhere by a pressure, without superficial motion. It requires to be more tenacious and hard, but less tough and greasy than paint. This, and the other qualities, are communicated to it by a proper choice in the kind of oil, and by the preparation of boiling. Linseed and nut oil are the most suitable. The latter is the fittest for black ink; but the boiling imparts to it a brownness, which injures the brightness of red ink. The other oils dry too slowly, and inks made of them come off and smear the paper, or the oils sink into its substance, so as to surround the letter with a yellow stain.

The oil is boiled in a pot large enough to hold at least half as much more to prevent boiling over. While boiling, it is constantly stirred with an iron ladle; the surface also is kindled, and allowed to burn for half an hour, in order to consume and separate more completely the inflammable parts on which the greasiness chiefly depends. After the burning is extinguished, it is allowed to boil some time longer. A thick kind is made for use in hot weather, and a thinner for cold. Both go under the name of varnish. The thick varnish is known to be of the due consistence when it draws into threads between the fingers like weak glue. It is viscous, like a soft resinous juice. A proportion of turpentine or rosin is boiled along with it, to give it body, and increase its drying quality; some add a quantity of litharge. But as these admixtures render it extremely difficult to cleanse the types, it is much better to employ varnish which has acquired the same property merely by age.

The colouring matter generally employed is lamp black, two ounces and a half to sixteen ounces of the varnish. They are ground together like paint. It is probable that the varnish has acquired, by the preparation, a gummy quality, and loses in part its oily constitution, a change which gives it the property of adhering to wetted paper. The substance left, when dried, is tough and flexible, and little disposed, either to mix again with oil, or with water. The gummy and oily matter were thought by Dr. Lewis to be so proportioned, as to defend one another in some degree against the menstruum of each.
The preparing of printer's ink is a very delicate art, and hence it is in the hands of a few. The ink used in all parts of Great Britain is made in London. That which is used in France is somewhat different, and hence the French typography differs from the British. It has a brilliancy and distinctness which we cannot imitate, except by using the article prepared in France. Differences of opinion exist as to whether these properties are advantages or not. Some complain of them, as accompanied with a dazzling effect.

Ink used for printing from engravings by the rolling press, must have less of the adhesive qualities, and a greater degree of yielding softness; it must easily run into, and fill the hollow lines in the copper-plate, and at the same time be easily wiped off the polished surface of the plate, previously to the taking of the impression. The peculiarity in the manipulation of the varnish, consists in giving it less boiling than that which is to be used for type ink. Lamp black is improper for engraver's ink, as it communicates to it an inconvenient toughness. The charcoal blackening, such as that called German, or Frankfort black, supposed to be procured from burnt vine-twigs, or kernels of fruits and wine-leaf, is in highest reputation, as more free from grittiness than the ivory black of this country.

The preparing of engraver's ink does not require the same delicacy with that of printing ink. The black, indeed, requires to be well chosen; but when this is done, every engraver mixes up his own ink, which is not the case with the printer.

Our common writing ink is a substance of a totally different kind, both in its colouring matter, and its menstruum. The colouring matter is a tenacious substance, formed by precipitating iron from a saline solution, by the gallic acid and tannin, and the vehicle is water, slightly impregnated with a mucilage. But, though this is the radical principle on which ink is made, the preparing of good ink requires considerable nicety in the choice of materials, as well as skill in the manipulation. Although any salt of iron would give a dark precipitate, when treated with astrin gent matter, the only one which gives a good black is the sulphate, and the only form of astrin gent which answers is the gall nut. It is, indeed, often improved by conjoining it with a little logwood. It has been observed that many inks are liable to become pale or to disappear.

The learned and laborious Dr. Lewis instituted a series of minute experiments for the purpose of determining the just proportion of the different ingredients, and obtained some interesting chemical results. He found that equal parts of this salt, and of blue or Aleppo galls, gave an ink which, though of a good black when first used, became yellowish brown when the writing was kept for a moderate time; that in proportion to the quantity of the sulphate, the inks were less durable in colour; and that those in which the galls were in excess were most durable. Thus it appeared that the galls were the most perishing article in ink after it is applied to the paper, and therefore ought to be in largest proportion; that a durable ink should contain at least three parts of galls for one of the sulphate of iron; but when much above this proportion, they render the colour too pale.

The degree of dilution of ink admits of considerable latitude. The fullest and blackest colour is produced, when the water is just sufficient to cover the powdered ingredients. But 40 or 50 ounces of water, to one ounce of the metallic salt, and three of galls, make an ink sufficiently black for common purposes. Distilled or rain water was found, by Dr. Lewis, preferable to common water.

But white wine formed a blacker ink than water, and vinegar formed one still blacker than wine. Spirit injured the colour, and occasioned a precipitation of part of the colouring matter. A decoction of logwood instead of water, improved both the beauty and the deepness of the black. A piece of iron kept in ink for a length of time after it is made, improves its colour, probably by uniting with the sulphuric acid disengaged by the galls. In order to give ink a greater consistence, and enable it better to keep the colouring matter suspended, gum arabic is added, and it probably preserves the black matter in a state of greater tenuity, preventing, by its mechanical qualities, the attraction of cohesion from forming that matter into larger particles, and thus preserving it nearer a state of solution than it would otherwise be. The gum also prevents it from spreading on the paper. A greater body of colour is thus collected on each stroke, and the writing retains its blackness much longer than when none is added. A common addition is sugar; but its only good quality is that of communicating a shining gloss to the writing. It renders the ink more tedious in drying, and a sufficient glossiness is obtained by the gum alone. Dr. Lewis found that the addition of other metallic substances which had been sometimes recommended, such as sulphate of zinc, or of copper, injured ultimately the quality of the ink; and that the galls ought to be finely powdered, and not merely bruised, as some had directed.

The recipe of Dr. Lewis, deduced from his numerous trials for making good ink, was one ounce of powdered sulphate of iron, one of powdered logwood, and one of guin, with three of powdered galls, and a quart of white wine or vinegar, although water will serve common purposes. These ingredients are to be put in a glass or other convenient vessel not metallic, and the mixture shaken four or five times a day. In 10 or 12 days it will be fit for use, and sooner if in a warm situation; but it continues for a long time to improve if left without decantation. When it is separated from the powdery residue, it will be kept in a good state with greater certainty, if some broken galls, freed from the fine powder, and some pieces of iron, are put in it. Iron, however, is the only metal which it is safe to retain in contact with ink.

Leaden or copper vessels, when used for containing it, become dissolved by its acid ingredients, and part of the iron is precipitated. This fact appeared an anomaly during the prevalence of the doctrines of elective affinity, as explained by Bergman. As iron precipitates other metals from their solutions, it appeared contrary to all chemical principles to suppose that these other metals were capable of precipitating iron. But, since the investigations of Berthollet have imparted a new, and in some respects more correct, light to the doctrines of chemical affinity, we acknowledge that the acid exerts a simultaneous attraction for both metals, and dissolves a proportion of each, depending on their relative affinities. These precautions relating to ink were clearly laid down by Dr. Lewis as the result of practical experience, while the doctrines of Berthollet were as yet unknown, and in that state of science such precautions appeared inexplicable; but, in its present state, they are recognised as furnishing a beautiful illustration of them.

In order that ink may be more durable in the manuscript, the paper may be advantageously dipped in a solution of galls; this obviates the fading on the back of the paper; i.e., in the part to which the ink has sunk deepest, where that change is most apt to commence. Dr. Lewis found this to be very effectual in his experiments. Others have recommended that the paper should
be dipped in prussiate of potassa, which makes any tendency to change of colour to consist in the acquisition of a deep and rich blue tint.

But, as this species of ink, after the best preparation, is apt to decay, Dr. Lewis made attempts to form one of still more durable materials. He found that a composition of black carbonaceous matter, such as lamp black, with varnish, and half the weight of a thick mucilage of gum arabic, formed an ink which, though it was easily rubbed out with water on common paper, proved in every respect durable when applied with a pen to bibulous paper. The manuscripts of the ancients were written with lamp black and gum; and the Chinese use a similar composition for all their writings, the same which is sent to Europe under the name of China ink, which they apply with a stiff hair pencil, fixed in the end of a reed. When vinegar is used instead of water in tempering it, the ink sinks deeper into the paper. Dr. Lewis ingeniously suggested as an improvement, the union of the ancient with the modern method, by adding a small portion of the ancient composition, or of Indian ink, to our common ink. In this case, cotton must be used in the ink-stand, to prevent the settling of the black powder.

These methods are sufficient to secure every advantage, where the effacing of manuscripts is not done by design. But it has become, in recent times, an object, on many occasions, to guard against frauds of obliteration. These are more easily executed since the discovery of the oxymuriatic acid, and its power in effacing all inks made of the gallic acid, or vegetable astringents, with iron. For preventing the possibility of this, when it is dreaded, an admixture of lamp black or other burnt carbonaceous matter is effectual, and ought to be in larger proportion than on other occasions. Finely ground indigo is recommended by some along with the lamp black. Others employ finely levigated manganese, and others a solution of indigo in concentrated sulphuric acid. The editor of the Annales des Arts, vol. ii. p. 106, observes, that the common ink may be rendered incapable of being discharged by any action which the paper can withstand, if, instead of water, the expressed juice of green vegetables be used, such as the lacthyris, the sambucus niger, or common grass.

Indian ink.  
Indian or China ink, being an article possessed of valuable properties, experiments were made by Dr. Lewis to analyze and to imitate it. He found that the adhesive ingredient in it was an animal glue, and he formed very good imitations of it by means of glue and lamp black. The superior delicacy of the imported article seems to depend on the black. It brings different prices, according to its fineness; and this depends on the kind of oil from which it is produced. Various oils are burned in that country, in chambers made for the purpose. Duf Halle gives three receipts for this composition, on Chinese authority. In one of them, the conglutinating ingredient is gum tragacanth; this must have formed an ink different from that brought to us from China. In another it is thin size, and in a third the size is mixed with a decoction of certain vegetables, which probably impart no quality excepting smell.

Indelible ink, for marking linen, without being liable to obliteration by washing, is merely a solution of nitrate of silver, with which the letters are traced after the part to be written on has been dipped in a solution of soda, and dried with a strong heat.

Inks of various colours may in general be made by using a strong decoction of the ingredients used for dyeing, mixed with a little alum and gum arabic.

Red ink from an infusion of logwood.  
Green ink from a solution of acetate of copper, with gum arabic and white sugar.  
Blue ink from indigo, ground with white of eggs, and brought to the due consistence by water.  
Yellow ink from an infusion of crocus, with alum and gum arabic.

Sympathetic ink is a substance with which writings may be formed, which are invisible till they are subjected to some process, which immediately renders the whole distinct. This purpose was fulfilled among the ancients by means of milk, or some other viscid substance, which was rendered legible by means of soot thrown over the writing; part of it adhering wherever the lines were drawn, while from every other part it was blown entirely off.

There are some articles employed for this purpose, which are rendered visible by the addition of a substance which acts chemically. The materials of writing ink may, for example, be employed in a separate state. Invisible words may be first written with a solution of the sulphate of iron. If a rag, dipped in a decoction of galls, be drawn over them, they become immediately legible. If this be afterwards rubbed over with sulphuric acid, it is effaced. But the application of a saturated solution of potassa will make it re-appear like yellow writing.

The golden sympathetic ink consists of a solution of gold in nitro-muriatic acid, diluted with six times its quantity of water. Letters traced with this are invisible; but when a similar solution of tin is applied to them, the writing appears in the form of beautiful purple letters. Nitromuriatic acid is now capable of effacing them, and the re-application of the muriate of tin will restore them. Letters made with the muriate of gold, indeed, become spontaneously visible when exposed to the air. This, however, requires several days, and, if kept closely shut up, they remain invisible for two or three months. The acid evaporates, and leaves a violet oxide or submuriate. Nitrate of silver affords invisible letters, which become black by long exposure. There are many sympathetic inks which are rendered visible by exposure to a fire. Solutions of muriate of ammonia, and various other neutral salts, act on paper by means of heat, in such a way as adapts them to this use; but the letters become, in process of time, confused and illegible.

The best sympathetic inks are those made from ores of arsenic, bisnuth, or cobalt. Diluted nitric acid is poured on arsenic ore, and afterwards carefully decanted, treated with nearly half the quantity of dried muriate of soda, and evaporated. Letters or figures formed with this are invisible till held near a fire, which renders them visible, and of a beautiful bluish green colour. This disappears again when it is removed from the fire. Alum, with the sulphate of soda, used instead of muriate of soda, renders the substance red. Borate of soda, or nitrate of potassa, also makes the letters appear red.

The nitro-muriate of cobalt forms a similar ink, which appears on exposure to heat, and disappears in the cold. The heat applied to it, however, must not exceed a certain strength, otherwise the letters become permanently visible both in heat and cold. These inks are employed for making amusing landscapes, in which the trees acquire a summer foliage as often as they are brought near a fire. A sympathetic ink may be obtained from fresh urine, evaporated, then dissolved in nitric acid, and saturated

1
with ammonia or its carbonate. Lines drawn with this become visible, of a fine red, on exposure to a gentle heat. Sulphate of zinc applied to them gives them a rich yellow. This ink must be applied, however, immediately after it is formed. It becomes deteriorated in so short a time as twenty minutes. (H. D.)

INLAND NAVIGATION. See Navigation Inland.

INN, VALLEY OF, a valley of Switzerland, in the canton of the Grisons, bounded on the north-west by the mountain chain of Septimen, Julien, Scornia, Fluela, Varaina, and Salva; to the west by the Maloggia; and to the south-east by the chain of Bernina. It extends eighteen leagues in length, from north-east to south-west, and is traversed throughout by the river Inn. This valley is named Engadine in German, and in the language of the country Engiadina, which some etymologists conceive may be derived from words signifying the head of the Oen or Inn. It is one of the richest and most beautiful in Switzerland, and is divided into two portions, the Higher and Lower Engadine.

As the valley of the Inn belongs to the primitive Alps, and lies in a high situation, the climate is rude during a long part of the year; but almost every different quarter has a different climate. Winter continues nine months, and the inhabitants can seldom dispense with fire in their apartments in the course of the other three. The sun is never oppressive: a week seldom elapses without heavy frost during the warmest weather; and sometimes the hottest day is succeeded by freezing in the night. Snow frequently falls in June or July; the lakes freeze from the end of November until the month of May, and snow lies five or six feet deep. Earthquakes, nevertheless, are frequently felt, the shocks proceeding in a direction from east to west.

The river by which the valley is watered, rises in a small lake called Lugin, or Lugin, behind the mountain Septimen, and is at first called the water of Oen. It falls into the lake of Sils, at Siglio; leaving which, it is united to a much larger torrent, descending from the glacier Muretto, where several geographers place the source of the Inn. After being enlarged by a multitude of streams, and passing through the valley to Thurg, it rolls its waters across the plains of Bavaria. At Parsan it unites with the Danube, there a much less considerable river, when it loses its own name for that of the other. The Inn is a beautiful limpid stream, characterized by fine and picturesque scenery. There are twelve small lakes in the valley of the Inn, and twenty-five lesser valleys terminate within its boundaries.

The Higher Engadine extends seven leagues in length, from Mount Maloggia to Mount Canassia; but its level ground is only from a quarter to half a mile in breadth. It universally presents the appearance of having been hollowed out by the action of the waters. It is traversed by primitive beds of calcareous stone and gypsum, and contains argil of all colours.

The Lower Engadine extends eleven leagues from Braid to Pont St. Martin, and is more fertile and populous than the former. Many thick forests of pine clothe the valley; and the southern sides of the Lower Engadine are covered by those of fir, from which constant supplies are drawn for the salt-works of the Tyrol. Barley is the only grain which is cultivated. Legumes succeed well; but there are few fruits, and the climate, in general, is not favourable to vegetation. The bread baked here is made to last three, or even six months, and is hence extremely hard.

The inhabitants of the valley are of agreeable physiognomy, laborious, active, and in a comfortable condition. Those, however, of the Higher Engadine, are represented as superior, in every thing, to the inhabitants of the Lower Engadine. They dwell in several villages, of which Soglio is computed to be at the height of 6300 feet above the level of the sea. All the villages of the high district contain good inns, those of the low district are not equally so. Agriculture is prosecuted to a much greater extent in the latter, but there seems to be no manufactures of any importance. A particular excellence, known by the name of spirit of ino, is distilled from a plant which is much prized in Italy for its musky and aromatic odour, and the plant itself is exported, in considerable quantities, to Saxony and France, for the same purpose. The population of the valley is annually decreasing, and luxury is making rapid advances. There is a considerable preponderance of females, probably from the resources offered for the enterprize of the males being too limited; whence they have to perform many of the offices, which would more naturally fall to the province of the other sex.

Most of the Protestant clergy of the canton are natives of the Engadine; and the Protestant religion is professed throughout the valley, except by the community of Tarasp. The administration of justice is better in the High than in the Low Engadine, where the judges are accused of too great a propensity to severe punishment, and resorting too readily to torture. Likewise, it is said, that the laws are very defective, and law suits tedious and expensive. Emigrations are not so general from the former as the latter. The natives repaired to Venice in great numbers from the thirteenth century, and, in the year 1614, several thousand shoemakers, all from the valley, were found in that city. But their entrance into the Venetian states was prohibited in 1766, since which time many have principally followed the occupation of confectioners. Carrying their inclinations habits to other countries, some are enabled to return, with considerable profits, to pass their old age at home.

The inhabitants of the valley have sometimes participated in the political disquiets of the neighbouring nations. All their villages were burnt by the Austrians in 1721 and 1722, and the valley became nearly deserted. Five years later, the Austrians were expelled by the Duke De Rohan; and the inhabitants enjoyed profound peace until the recent revolutionary wars which have agitated Europe. A French army having passed the frozen lakes in 1799, took possession of the valley, in the course of the aggressions of their government; and in Switzerland several conflicts ensued between them and the Austrians, by whom they were finally driven out in the year 1801. (c)

INOCULATION, in Medicine, the artificial production of an infectious disease by morbid matter, brought in contact with the animal fibre. This is practised, for the sake of inducing a milder form of disease than that which is the general consequence of casual infection, and for protecting the constitution against future attacks of the same disease.

Inoculation has been performed, for the sake of experiment, in various diseases which are known to attack the human frame only once, but in none with that marked success which has taken place in small-pox. Wherever it has been practised, it has greatly diminished the mortality arising from that disease; and hence has, for nearly a century, been in general use as a preventive of its dangerous forms.

Inoculation comprehends some of the most curious and interesting phenomena of the body.
INOCULATION.

Phenomena of physiological and pathological science, and therefore becomes interesting, both in a scientific and a practical view. We do not know all the causes of the differences in degrees of mildness of the same disease. Physicians are most generally inclined to ascribe them to previous differences in the state of the constitution of the person affected. It could not have been concluded, and scarcely even surmised \textit{a priori}, that a difference in the mode in which the morbid matter was applied, would have in this respect any marked effect. Far less could it have been supposed, that matter, in a fixed and moist state, brought in contact with an exposed living part, would have produced a disease milder than that which is generated by dry contagion, casually applied to the cuticle or volatile effluvia inhaled in respiration. These points of doctrine are only known in consequence of continual experience. It might be expected, that some extension of the knowledge of this law of contagion might enable us to insure to the attendants of the sick, a mild, rather than a severe form of other contagious diseases, where one or the other is unavoidable; but as yet we know nothing more than the gross facts connected with inoculation as actually practised. Even a plausible \textit{rationale} of the well known result is a desideratum in medical science. It might be ascribed to the minuteness of the quantity of matter injected; but this is hardly a probable theory, and does not seem in perfect accordance with some other facts attending the communication of contagious diseases. But it is highly satisfactory to find, that the beneficial effects of inoculation are so undoubted and so extensive in exempting society from the incursions of one of the most desolating diseases, or reducing the mortality of it within an incomparably narrower compass. It will, therefore, be interesting to take a retrospect of the history of this valuable discovery.

The small-pox had prevailed for several centuries in civilized Europe, before inoculation was generally known. It is not, however, one of the most ancient diseases. It was not known to Hippocrates, nor any of the old Greek or Roman authors. It is first mentioned by the Arabians after the establishment of the Mahomedan religion. The mode and principles of its production must, like all other points of the same kind, remain to us unknown, and the formation of conjectures on such a subject is a fruitless application of inventive genius. The existence of it cannot be traced farther back than to the siege of Alexandria in 640. But whether it originated among the besteged Egyptians or their Arabian invaders is not known. We are indeed told that traces of it have been found in some Chinese writings of much more ancient date, and also in some of the sacred books of the Gentooes; but these accounts are too general to prove the high antiquity of the disease, and are equally unworthy of confidence with the fanciful comments by which a similar testimony has been extorted from the Jewish writers. The only accounts worthy of being listened to are those in which this disease is said to have attacked the army of the Arabian and Abyssinian Christians at the siege of the pagan city of Mecca, in 522, about the time of the birth of Mahomet. But it was certainly unknown to the most intelligent writers till the siege of Alexandria by the Saracens. The history of its subsequent ravages was but imperfectly recorded. We only find occasional traces of them. Circumstances of that kind are often omitted in the historical page, but we have enough to show that this was one of the most formidable diseases to which society was exposed. Many persons of distinction are casually mentioned as having fallen victims to it. The time of its first introduction into Britain is not precisely known, but both here, and in every other country, it has been peculiarly destructive when it made its first appearance. It is said to have been imported to Europe by the crusaders; but it appears to have been of much earlier introduction. In 1520, it first visited some provinces of South America, and proved fatal to one half of the inhabitants. In Europe it continued to be, till the last century, the principal risk to which human life was exposed at an early age.

About that time the practice of inoculation first excited public attention. But this preventive had been previously known and resorted to in confined districts in different countries. The discovery of it must have been entirely fortuitous, and it is probable that the want of any analogy between its effects and all the facts previously known, prevented the attention of medical men from being duly directed to it. Hence it was for several ages under the management of poor old women, and other ignorant persons. After inoculation had been introduced into London in 1724, and excited much general conversation as a foreign invention, it was found, (to the great surprise of the learned,) that it had been known in South Wales as far back as tradition could be traced. And it was thus known, that it had been there communicated artificially, under the denomination of buying the small-pox, exactly in the same manner as in Africa and Turkey. When thus bought, a quantity of the matter was rubbed on the skin, or inserted by pins infected with it. Sometimes dry variolous crusts were held in the palm of the hand. In the Highlands of Scotland it was artificially communicated for many ages, by tying worsted threads contaminated with the matter round the wrists of children, and it was superstition imagined that it would not produce the desired effect unless purchased for a piece of money, or some other article, however trifling, in exchange. This was the case in different parts of Italy, France, Germany, Denmark, and Sweden. In China it seems to have been practised for more than 200 years, and still longer in Hindostan. The Chinese performed inoculation by introducing dried pustules with aromatics into the nostrils, a method less successful than that which has been in general use in other countries. In Hindostan this operation was practised by a particular tribe of Brahmins, by means of a slight puncture, over which they tied a rag impregnated with variolous matter, accompanying the operation with superstitious observances.

In 1701, inoculation having been previously in frequent use among the poor Greeks of European Turkey, was adopted by the higher classes in consequence of a very mortal small-pox which then prevailed at Constantinople. The knowledge of this fact was circulated in England in 1716, by a paper from Pylaerin, published in the Philosophical Transactions, and by Mr. Kennedy, in an essay on external remedies. But the subject was more generally impressed on the public mind by one of the letters of Lady Mary Wortley Montague, written from Adrianopole, for the purpose of introducing this useful invention into her native country. That celebrated lady had the operation performed on her own son. It was in 1721 that it was first attempted among persons of education in England. Dr. Jacob de Castro and Dr. Harris exerted themselves to recommend it. We must, however, consider the lady now mentioned as having the chief merit of the introduction of inoculation into Britain. It did not meet with a ready adoption among the generality of

Important statements.

medical men, who were rather inclined to despise it on account of the obscure origin of the invention, and the progress of it was somewhat unsteady. It was for some years forgotten from mere indifference, or held in dread in consequence of the remonstrances of eloquent and plausible adversaries. The inoculators were sometimes assailed by the most formidable invective. Mistakes occasionally arose among them in consequence of the imperfection of the knowledge of the subject under which they for some time laboured. Mr. Maitland, for instance, maintained that the inoculated small-pox was incapable of transmittal infection, and he encouraged persons indiscriminately to handle children under the inoculated disease, in consequence of which some received it in a severe or fatal form. Advantage was taken of such occurrences to misrepresent the whole motives of the advocates for inoculation; and the crimes of mercenary cruelty, and downright murder were imputed to them. A few theologians united their intertemporal denunciations to swell the general outcry. In performing this imaginary duty, the Rev. Mr. Massey maintained, "that the cutaneous disease of Job was produced by inoculation from the hands of the devil, and that the whole art was of infernal invention." One of its most powerful opponents was Dr. Wagstaffe, physician to St. Bartholomew's hospital, whose high character for learning and professional practice gave uncommon weight to his opinions. He condemned it on account of the uncertainty of the consequences, drawn from facts which had appeared only in one sort of climate. He denounced it as contradictory to reason, and maintained that, though some who were inoculated took the disease in a moderate form, others were either not affected, or so slightly, that no security could be expected against a future attack, while others had it in the most alarming and dangerous form, and died under it. He denied its power in securing the constitution against the disease in future. He condemned it as keeping up a focus of contagion from which much danger to others proceeded. He took advantage of the dissensions existing among its authors, as evidence that those positions were unworthy of confidence. Some cases occurred in which, after the inoculated small-pox, the disease was said to have been received by casual infection. These gave rise to much clamour against the inoculated disease as an insectile security, though they were generally found, on fair inquiry, to be cases of chicken pox. The argument was, on the whole, enveloped in much confusion, till Dr. Jurin fixed the attention of the public on the two important points in dispute, which were capable of being brought to the test of experience, and which, if established, were sufficient to supersede all theoretic reasoning, and all religious scruples. He first detailed the multiplied facts which showed that the inoculated small-pox secured the constitution against the disease in future, and then those which proved that the hazard of inoculation was much less than that of the natural small-pox. He stated, that the whole number of deaths, in London, for forty years back, was 903,708, of which 65,079 were occasioned by the natural small-pox, shewing that more than one-fourteenth part of mankind died of this disease, and as some must have died without having had the small-pox in any form, he concluded, from a judicious calculation, that of those who were seized with small-pox, two in seventeen, or nearly one in nine, died. But, by some actual inquiries into the history of numerous families, it appeared that the natural small-pox was fatal to one patient in five or six, while those who died of the inoculated disease were only one in 60. In the years 1721, 1722, and 1723, 474 persons were inoculated in England, of whom 9 died. In 1724, the number inoculated was only 40, of whom one died. In the following year, when the natural small-pox was very prevalent, and very mortal, 151 were inoculated, and in the following year 105, making 256 in these two years, of whom 6 died. In the next two years only 124 inoculations took place. Thus during the first 8 years of inoculation, 897 persons were inoculated. From statements, it appears that 5% of these had true variolous pustules, and 13 an imperfect eruption; in 39 no disease was produced by the virus, and 17 were suspected to have died of the inoculated disease. From domiciliary visits, it was discovered that of 18,229 persons who had been affected with the natural small-pox, 908 had died of it, i.e. one in six; whereas the deaths by inoculation, granting the utmost contended for by its adversaries, did not exceed 1 in 50.

Inoculation was first practised in Scotland in 1726 at Aberdeen, on eleven persons, by Mr. Maitland, who had come home from Turkey; and, as one of these cases proved fatal, a violent prejudice arose against it, in consequence of which it was for 20 years after this discontinued in that part of the country. At Dumfries, it was practised first in 1735, during the prevalence of a malignant variolous epidemic; but in other parts of Scotland it was not adopted till about the year 1738.

In Ireland, it was first introduced in 1729 by Mr. into Ireland, Hall, surgeon in Dublin, who inoculated 16 persons. Other 9 operations were performed about the same time, and of these the number that died was three,—a Decline in England.

In England, inoculation declined during the twelve years after 1726, i.e. till 1738. It was now, however, making considerable progress in the transatlantic world. The popish missionaries introduced it among the aborigines of South America, to whom the natural small-pox was highly destructive. In 1738, when a fatal epidemic prevailed in South Carolina, in consequence of infection imported in a slave ship from the coast of Africa, Mr. Monbray, surgeon, introduced inoculation, and performed it on 450 persons. He was followed by Dr. Kirkpatrick and some others, so that the number of the inoculated soon amounted to about 1000. Among these there were eight deaths. Dr. Kirkpatrick published in London, an essay on inoculation, in the year 1743. The practice was soon after introduced at Philadelphia, and in some of the West India islands, where it proved still more successful in checking the progress of a fatal epidemic. The accounts of this success contributed to the revival of inoculation in England in 1751 and the subsequent years. Sergeant Ranby had, in 1751, inoculated 1,600 persons. The writings of Dr. Mead and Dr. Frewen had considerable weight on the side of inoculation.

In 1746, a scheme was proposed by some public spirited characters, among whom were several persons and inoculation high rank, for a hospital for the reception of patients casually affected with small-pox, and another for inoculating the poor. This was immediately opened under the designation of "The Middlesex County Hospital for small-pox." Other two were soon after established, and their plan was greatly extended. In 1750, there was an institution, which consisted of three houses, viz. one in Old Street, for preparing the patients for inoculation, another in Frog-lane, Islington,
INOCULATION.

for receiving them when the disease appeared, and a third in Lower Street, Islington, for patients labouring under natural small-pox.

The opinions which then existed on the necessity of a long preparatory course of medicine rendered the business of this charity tedious and expensive. The patients were subjected to this process for a whole month; and, that they might not be exposed in the interim to any casual infection, a great number was inoculated on the same day, and no inoculation was performed till these were removed from the house of preparation, and this house subjected to a process of purification. Thus the inoculations were only once in seven weeks, and the patients were subjected to confinement for two months. This institution had to contend with the prejudices of the populace, who regarded it as a source of calamitous infection to the neighbourhood in which it was established, and insulted the patients in the grossest manner as they passed along after their dismissal. Application was even made to the Lord Chancellor to have it suppressed as a nuisance. This of course proved effectual.

Dr. Madox, Bishop of Worcester, who was made president of that institution, was a most zealous and enlightened advocate of inoculation, and preached an eloquent sermon in recommendation of it, exhibiting a luminous contrast to the diabolism which Massey had poured on it thirty years before, and it so happened, that it was delivered from the same pulpit. It was afterwards published, and contributed considerably to the promotion of the cause. It now made an uninterrupted progress, though still opposed with equal violence by a few individuals. Its friends watched assiduously the attacks of the enemy; divines, as well as physicians and surgeons, co-operated in vindicating and recommending it, and all opposition ceased, except from persons of very low character.

In France, it made a similar progress, in which it had to encounter opposition, which was apparently formidable, but betrayed equal weakness and absurdity as that which we have already described. Dr. Hequet expressed so great an antipathy to inoculation, as to question the lawfulness of performing a certain operation which goes under that name on (trees), and stigmatized it as contrary to the laws of nature, and strongly savouring of magic.

In Holland, inoculation was begun at Amsterdam in 1748, by Dr. Trouchin, in his own family. It was not, however, brought into general favour in that country till 1764. It was afterwards greatly promoted in the Low Countries by the favorable accounts of the American inoculation, as given by Dr. Tenet, an American student, in his Thesis published at Leyden, in which he stated that of 8327 persons who had been inoculated in Pennsylvania and the neighbouring provinces, only 19 (making one in 438) had died. In Denmark, it was introduced by Dr. D. Argent, and in Sweden by Haartman. In both of these countries, its progress was greatly accelerated by the paternal encouragement of their respective courts.

In Switzerland and Italy, it was introduced about the year 1754. In Germany, it was begun at Hanover almost as soon as in England. The Prussian and Austrian states were the last in which it was received, as it was opposed by De Haen of Vienna, and discouraged by the occurrence of three fatal cases in the beginning of Professor Mechel's inoculations at Berlin.

It was in 1768 that it was first known at St. Petersburg, though the small-pox had destroyed two millions of persons annually in the Russian empire. In that year, it was established in the Russian dominions by Dr. Dimsdale, who was sent from England for that express purpose, and returned to his native country loaded with wealth and honours for his services. It was first established in Spain in 1771, though it had been practiced for many years before at Cadiz, an obscure town of that kingdom.

The principal writings by which this subject was elucidated, in our country, were those of Dr. Kirkpatrick, Mr. Burgess, and Dr. Monro. Dr. Kirkpatrick published a second edition of his work, with large additions, in 1761. In 1764, Dr. Monro published his account of the inoculation of small-pox in Scotland. The number then inoculated in this part of the kingdom, was 5554, of whom 73 died, i.e. one in 76. In the northern isles, 112 had been inoculated in the middle of winter, and, though they went abroad barefooted in snow and ice, not one of them died.

The public attention was long and powerfully excited by the Suttonian method of inoculation. This was introduced by Daniel Sutton, an eminent surgeon in Ingeston, Essex. It consisted chiefly in shortening the period of medicinal preparation of the patients for the operation, from a month to a few days, and in keeping them in the open air during the whole process of the eruption. In this he succeeded to his wishes.

The advantages of his plan attracted so many patients, that in the first year he cleared 2000, and in the second 6000 guineas by his fees. In 1767, he removed to London, but did not meet with proportional encouragement. The medical success of his practice was greatly exaggerated by his friends. It was maintained that he had a secret medicine which gave him perfect command over the number of pustules produced, and rendered the inoculation absolutely exempt from danger. The few deaths which occurred were ascribed to causes independent of the disease. His plan of preparation consisted of abstinence from animal food and fermented liquors for a fortnight. A dose of a powder, which appears to have been mercurial, was given three several evenings during this fortnight, and next day a dose of cathartic salts, during the operation of which (except only the fruit) was prohibited. The months of May, June, July, and August, were preferred as the most seasonable for the inoculation of delicate subjects. The autumn was reckoned the most unfavourable season; and aguish habits the least safe. Scrobutic constitutions he considered as not objectionable. He inoculated with recent moist matter, introduced under a piece of elevated cuticle; and he is said to have often inoculated with a lymph taken from the arm of another inoculated patient, before the eruption of the small-pox. A pill was given on the night following the operation, and every second night till the eruption fever made its appearance. The same diet used during preparation, was continued in the course of the disease. During the fever, if there was no perspiration, drops were administered; which brought on profuse sweating. In cases of high fever, he gave a powerful powder or pill, the composition of which he concealed; cold water to allay dry febrile heat; and balm tea during the desired perspiration. When the sweat abated, and the eruption appeared, he ordered exercise in the open air, and milk gruel in unlimited quantity. The diet was kept low in proportion to the symptoms of local inflammation. Sir George Baker, who interested himself in some inquiries into the Suttonian practice, ascribed the success attending it chiefly to the free and cool air, which formed part of the regimen, and corresponded with the plan, which...
INOCULATION.

Vaccine inoculation.

Sydenham had found most successful in the natural small-pox. Others ascribed the success of this plan to the preparatory steps by which the patient was predisposed to perspiration, and the profuse perspiration afterwards induced, previously to the various eruption. Mr. Sutton's most partial advocate, the Rev. Mr. Houlton, (who was a chaplain settled under that gentleman's patronage at the place where his inoculations were conducted,) maintained that the whole process was unknown to all except the discoverer himself. Mr. Chandler asserted that the success of Mr. Sutton arose from his taking the matter at a very early stage, before it had been ultimately variolated by the succeeding fever. Baron Dimsdale explained, in perspicuous language, free from mystery, what he considered as the most eligible way of conducting inoculation. This author preferred matter taken during the eruptive fever, as the most active; and he preferred it taken from the place of inoculation, rather than from the other pustules. He describes the appearances at the different stages, with the corresponding prognosis, and appropriate treatment, the basis of which was the same with that of Mr. Sutton.

If the variola inoculation had continued to be equally important, we should have reckoned it our duty to insist still more largely on the preceding particulars. But this has ceased to be the case, not indeed from any failure of this form of inoculation, but from the substitution of another, which is still more advantageous. For a more particular account of the preceding part of the subject, we refer to the works which we have already mentioned, and also to the interesting History of Inoculation of the Small-pox, by Dr. Woodville, which, in a great measure, superseded every other to the modern reader. That work abounds in apt quotations, and is, on the whole, one of the most interesting specimens of medical and literary history with which we are acquainted.

We proceed to describe the form of inoculation now practised, which is commonly called Vaccination, or the Cow-Pox, one of the most brilliant discoveries of modern times, and which, at present, deserves a great interest from the scope which it still affords for speculation and experimental inquiry. It is founded on an extraordinary power possessed by a disease incident to the cow, and capable of being communicated to man, viz, a power of obviating the susceptibility of the system to small-pox. The existence of such a power, derivable from such a source, though often asserted by individuals, appeared incredible to persons most extensively acquainted with all the facts in pathology received among the learned, and the accounts of it were disregarded as vulgar fables. Since it has been ascertained, it must be considered as a death-blow to that sceptical incredulity which gratuitously rejects all novel suggestions, if previously to their plausible introduction into intelligent circles, it is too common to find medical men, whose information extends no farther than the routine of the day, cherishing their self-complacency with a semblance of systematic reasoning, and asking with incredulity, when any thing new is proposed, what good it can do? This spirit contracts greatly the sphere of salubrious expedients. We have no right to deny the existence of a power till we have disproved it. We have no right, indeed, to assert the existence of any power without evidence; but we may figure to ourselves the possibility of it, for the purpose of instituting experiments, or watching coolly the results of experiments made by others. After the discovery of the cow-pox, we find, accordingly, that the shock given to incredulity produced among its enthusiastic advocates a fertile suggestion of experiments, and a description, by anticipation, of numerous supposable discoveries. We cannot, however, advance as a point in science any principle which has not been actually ascertained. The truths known to us respecting the cow-pox are worthy of the attentive contemplation both of the philosopher and the philanthropist, and furnish matter for further research, as equally subservient to the extension of science, and the securing of additional advantages to human society.

For this discovery we are indebted to the now celebrated Dr. Jenner. It was previously known among persons concerned in several large dairy farms, that the disease, when received by accident from the teats of the cow, protected the human system against small-pox. Inoculation with it is said to have been practised in some instances by obscure individuals. Several years before Jenner wrote on the subject, some eminent physicians had heard of it, and mentioned it casually in their writings, but never with that pointed seriousness which was suited to so great an object. Dr. Jenner was the first who wrote a treatise for the express purpose of bringing it into view, and extending its medical application. This was in 1798, and the treatise was entitled "An inquiry into the Causes and Effects of the Variolae Vaccinae, a Disease discovered in some of the western counties of England, particularly Gloucestershire, and known by the name of the Cow-Pox." He did not blazon his discovery with the enthusiastic odes of Pythagoras. He exhibited the facts with that philosophic coolness which placed a just confidence in the candour and the enterprising spirit of the age; and he quickly found a band of warm co-ad joiners in the investigation of the subject, and the extension of the knowledge of it. Among these, Dr. Pearson of London was one who united much zeal with enlightened caution. He collected a copious body of information: he urged several important inquiries, and he availed himself extensively of his opportunities of ascertaining the laws of cow-pox by experiment. It would be unsuccessful to mention the names of many others who were conspicuous for their exertions in the same cause. In all parts of this island, and in every Rapid country of the civilised world, it was hailed by enlightened men as an important discovery, and they eagerly sought for opportunities of giving it universal currency. It was sent to the most distant countries, and spread even among the most unpolished nations; and it is now problematical whether any tribe on the face of the earth has not already experienced its beneficial operation. Prejudices have existed against it, but have been generally subdued by the gradual introduction of correct habits of thinking. Alarms have indeed been sounded against it, even by men of liberal education. Instances of this, however, have been few. They have arisen from accidental occurrences, rashly construed into the operation of constant natural causes. Zeal was precipitate in its movements on both sides of this momentous question; and the unblushing contention for fame, which on some occasions appeared, was ridiculous, and worse than boyish. The effervescence which controversy produced has gradually subsided. The inoculation with cow-pox has gained ground; facts of all kinds that occur relative to it are coolly observed. We cannot, however, boast of being in possession of a satisfactory knowledge of all the laws of vaccination. Occurrences occasionally arise, which create a doubt concerning the exact extent of its effects, both in exciting and in preventing disease. We shall, therefore, in the re-
INOCULATION.

Vaccination

Dr. Jenner's account of inoculation in the horse.

The remainder of this article, give an account of the principal points which have been ascertained, and take notice of some desiderata which are not yet fully supplied.

It was maintained by Dr. Jenner, that this disease is never of sporadic origin in the cow, but is derived from a disease of horses called the grease, by the application of the thin secretion yielded by that disease in its earlier and less conspicuous stages. Several presumptive evidences of this connection are given by him. Some experiments made by subsequent observers gave a different result. Negative evidence, however, is less to be trusted than that which is positive; and we have the respectable authority of Dr. Loy for believing, that this matter is capable of communicating the true disease to the cow, and through it to the human system; nay, that without passing through the cow, the virus taken from the horse at a particular stage of the disorder, imparts the real cow-pox to the human subject. Whether it ever originates in the cow independently of the horse, is a question of more difficult solution, as all the outbreaks of contagious diseases are enveloped in some obscurity.

In the cow, the disease appears in the form of irregular pustules on the teats. At their first appearance they are commonly of a palish blue, or rather of a colour somewhat approaching to livid, surrounded by an erysipelatous inflammation. These pustules, unless remedied by caustic applications, or other effectual means, degenerate into tedious and troublesome phagedenic ulcers.

This disease is transferred to the hands and wrists of the persons employed in milking. It appears in the form of blisters, similar to those which arise from burning. Their shape is circular where the situation will admit of it. Tumours are formed in the armpits. Various febrile symptoms arise, as shivering, pain of limbs, vomiting, headache, and delirium, which continue for several days.

When communicated by inoculation, this disease assumes a milder aspect, partly in consequence of the matter being less extensively applied, and partly in consequence of the parts in which it is inserted being less disturbed, and having a thinner cuticle than the hands. The disease communicated by inoculation is much more regular in its appearances than the case. About the third or fourth day, a small red spot appears in the punctured part, which gradually becomes more florid, and is slightly hardened and swelled. On the fifth or sixth day, this spot is converted into a small white vesicle. In two days this is much increased in size, and generally acquires a diameter of one-third or one-half of an inch. It has elevated edges, and, in the centre, a small depression, which is soon surrounded with a narrow crust. This last circumstance has been ascribed to the artificial puncture; but we have found a similar appearance in those rare cases in which other vesicles arise beside that which is formed at the inoculated part. On the eighth or ninth day, a circular inflammation appears around the vesicle, which increases for three days, and is sometimes half an inch, sometimes two inches in diameter. On the eleventh or twelfth day, this inflammation begins to disappear, first at an intermediate place between the vesicle and the outer margin of the red areola, producing the appearance of two florid concentric rings, one in contact with the vesicle, and another at a distance, like a lunar halo. The vesicle becomes harder, and of a dark brown colour, and, after the inflammation is gone, is converted into a horny crust, which adheres for a time, and afterwards separates, leaving a raw-looking depression, which continues to be distinguishable through life, being either somewhat depressed, or merely of a whiter colour than the neighbouring skin.

The appearances are subject to some slight varieties. Variations. One of these is a copious eruption of minute pusular on the inoculated arm, about the third day. This goes off in a few days. It most probably arises from some peculiar irritability in the inoculated subject, and is not generally found to bring after it any disadvantages.

In some instances, a copious pustular eruption has appeared over the whole body, which has given rise to eruptions, interesting discussions. These chiefly occurred under the practice of Dr. Woodville, at the small-pox hospital in London, and hence were ascribed to some influence of variolous matter, or a variolated atmosphere. They are, with greater probability, considered by Mr. Bryce as cases of true small-pox. We have, however, seen two cases of general eruption, one of which was copious, and the vesicles, though smaller than that which usually arises at the inoculated part, were distinguishable from those of small-pox by a minute central, and apparently depressed crust, which resembled the vaccine vesicle. From one of these, matter was inserted in the arm of another child, and produced the real cow-pox. Such cases, however, are extremely rare. The greater part of those in which pustules appear over the body, are cases in which the infection of small-pox has been received into the system previously to the inoculation, has been silently operating, and at last shown its symptoms in this form. Matter taken from such pustules for inoculation, has, accordingly, produced the true small-pox.

The febrile symptoms attending cow-pox are some of the most distressing in that disease, and are copious, and continued for a considerable space of time.

Two important questions are involved in this subject. First, Is the cow-pox perfectly safe? and, 2d, Does it afford full security against small-pox?

Is cow-pox mildness when compared to the inoculated small-pox? The latter has much fever, and is acknowledged to be sometimes fatal. A slight fretfulness or uneasiness for about 24 hours, or less, is all the fever that generally attends inoculated cow-pox; and it is a great point of advantage, that the matter of this disease has died. Deaths from cow-pox are remarkable, and may happen from other causes; while the cow-pox runs its course; but even this is an infrequent occurrence; and some have indulged fancy so much, as to think it probable that the cow-pox increased for that short period the average chance of human life, and thus was not only no disease, but an additional confirmer of the constitution against every contingency.

But, though never fatal, the cow-pox may be sup- posed capable of generating other diseases, either immediate, or on some future occasion, or of making the system obnoxious to some diseases in a more severe and dangerous form than they would otherwise assume. Some temperate enemies of cow-pox endeavoured to cutaneous explore it, by describing it as capable of producing that rare, loathsome cutaneous affection, the itch; and, that they might the more fully substantiate their point, added, that this itch was cured by the same means as the common pox. This last observation evidently took away the whole force of their objection. Who would hesitate to employ the cow-pox, though succeeded by an itch which required a few rubbings with sulphur ointment for its removal, in order to avoid the small-pox—a disease which combines so much greater loathableness, with imminent danger of death, and of hideous permanent deformities? Cases of this sort have certainly occurred.
The practitioner has told the parents that the eruption had no connection with the cow-pox, that the children had caught the itch, and ought to be treated for that complaint. The parents have taken offence at such an imputation, and remained unshaken in their opinion that the eruption was generated by the cow-pox; and unhappily, this contest has produced a remissness in the use of remedies, which ended in a permanent liability to cætonous eruptions. We apprehend that such inconveniences would be avoided, if practitioners would admit the occasional existence of such a sequela; and, without offending the delicacy of a parent, prescribe, upon this principle, the same remedies which are found effectual in the disorder now mentioned.

The cow-pox has been accused of giving origin to the symptoms of scrofula. This accusation we believe to be wholly unfounded. Some have even maintained that it powerfully corrects the scrofulous diathesis, and the one doctrine appears at least fully as well supported as the other.

It has been remarked by some, that of late years, the measles have been more dangerous and fatal than in former times; and this circumstance has been supposed not an unlikely consequence of the practice of the new inoculation. Till we see further proof, we cannot acquiesce in this suspicion. Investigations of such laws of disease, however, are important. Accurate comparative observations should be made on the varieties of subjects seized with measles, before we admit any such conjecture to possess the least plausibility. The generally increased mortality of measles is in itself not well established. It often appeared in the form of a very fatal epidemic before vaccination was discovered; and it is well known that in this respect the epidemics of different years, and different series of years, differ materially from one another. We have no better reason for suspecting the cow-pox of exposing the system to any disadvantages in compensation of the protection which it affords, than for attaching such an imputation to any article of diet or of medicine which we are in the daily habit of employing.

The other question is one of considerable magnitude. Does the cow-pox give effectual security to the human constitution against small-pox? That it does so in many instances, is fully ascertained. The evidences of it are innumerable, and in the individual cases they are in general absolutely decisive. Apparent exceptions, however, have occurred. Reports of these damped a little the ardour of Jenner at an early stage of his inquiries. But, conceiving it improbable that nature was in this instance capricious, he laboured to discover the true cause of failure. He found some circumstances to have occurred in the unsuccessful cases, to which he ascribed it; and on these he established some discriminating marks between the false and the true, the imperfect and the perfect cow-pox. He considered the occurrence of febrile or constitutional symptoms as essential to the complete security of the patient; and in this point, he was followed by Dr. Pearson and others. It must be acknowledged, however, that this may be a source of considerable hesitation. The febrile symptoms are acknowledged to be generally slight; and we may believe in the existence of an influence extended universally over the system, although no such symptoms are produced. On the other hand, uneasiness, fretfulness, and fever have arisen from a local disease, which acts only through the medium of sensation, or fugitive irritation. If to these circumstances we add, that a vaccinated subject is only occasionally seen by his medical attendant, and that the reports of mothers and nurses are often influenced by fancy, by carelessness, or by a wish to please—we shall find little satisfaction in attributing to febrile symptoms as affording a sure diagnosis. The world, is, therefore, under the highest obligations to Mr. Bryce of Edinburgh, who, in his treatise on cow-pox, has proposed a test of a much more ascertainable kind. It consists in making a second insertion of the vaccine matter at the end of the fifth day, from the first inoculation, and observing whether this produces a vesicle of its own, which is smaller than the first, and follows the same stages, but with an accelerated progress, so that the areola surrounding the two vesicles is formed nearly at the same time. These appearances will show that the influence of the original inoculation extends beyond the part operated on, so far as to comprehend the site of the second insertion. In order that it may be ascertained to be universal over the system, it may be some improvement to make the second at a part of the body the most distant possible from the first. By this test, we discover in what instances the modification to which the system is subjected is not merely local. Where no effect follows the second insertion, we are uncertain of this fact. If a vesicle is produced, but is not modified in its appearance and progress in a manner different from the usual course of the first insertion, we conclude that the constitution has not received the requisite change. This accordingly has sometimes happened where the first vesicle has been accidentally broken. We do not know if it is even liable to occur where the progress of the first vesicle is apparently regular. If not, we should conclude that no test, besides the regularity of the local appearances, would continue to be requisite. These important points may be numbered among the desiderata of this part of pathology. It is rash to assert that this difference would have taken place in any particular instance, merely because we find the patient afterwards seized with small-pox. That a person who has passed through this test in the most satisfactory manner never can be seized with small-pox, is a principle which ought not to be confidently anticipated, but only inferred after the amplest experience. Mr. Bryce's test is principally to be valued for the important improvement which it affords in the investigation of the subject; and for the pleasing light which it throws on the pathology of the animal economy. With respect to the advantages which it promises for distinguishing imperfect from perfect vaccination, it is certainly a priori, much superior to that of watching for febrile symptoms. Such symptoms might arise from the temporary commotion of a great central organ, but the phenomena which occur in that test, evidence an important change in the dispositions of the most minute fibres in which the functions of secretion and assimilation are active.

The occasional alleged failure of vaccination in securing the constitution from small-pox has been sometimes thought to arise from the manner in which the operation has been performed. If this were the case, we should naturally look for some definite variations of the subsequent effects, corresponding to the deviations from the best method of inoculating. But there is a looseness in the causes by which the failures are accounted for, which shows that something still remains to be explored.

If the vesicle, when ineffectual, were always distinguishable by its appearance, no dubiety could occur. It is therefore somewhat satisfactory to be told, that the spurious pustule is more elevated and opaque than

Vaccine Inoculation.

Mr. Bryce's test of a constitutional affection.

More precise information desirable.
INOCULATION.

The genuine, and more rapid in its progress; that it is not cellular, nor surrounded with a distinct circumscribed areola, nor converted into a dark shining scab. If these appearances are observed to take place, we, of course, put no confidence in the preventive powers of the affection induced. But it would be more satisfactory to have a precise knowledge of the causes even of this variation. These causes, however, are merely enumerated in a mass. Such a pustule is said to occur instead of the genuine cow-pox, "in those who have had the small-pox;"—it is said to be "produced by blunt or rusty lancet;—by matter taken from a spurious pustule—or from a genuine pustule at too late a period—or by matter which has been too long kept—or dried before a fire." (See the article Com-pox in Rees' Cyclopædia, written by Mr. Ring.) All these circumstances (excepting the bluntness of the lancet,) may be supposed to occasion a modification in the disease; but is it probable that they all agree in the kind of modification which they produce? A cautious inquirer will suspect that there is here some defect of observation; something presumed rather than discovered, unless numerous cases of this wonderful coincidence are minutely described; while the captious critic will exclaim that these assigned causes are only so many hedges behind which the wary vaccinator provides for himself a variety of shelter in case of disappointment. The only light in which reason and duty view them is, as so many motives for more extended inquiry. These remarks have indeed been elicited only by the explanations given of a vesicle which "carries its spurious character in its aspect." But we may derive instruction, by contemplating a specimen of that precipitation in forming conclusions, to which the medical world is liable in other points connected with this important subject.

The chief difficulty is, in order that vaccination may afford us the required advantages, we ought to be able to distinguish, "without difficulty," all the cases in which the constitution is secured by it either from disease or from danger. Vaccination has been chiefly in the hands of persons not medical; for this reason, it is among these that the most numerous failures have occurred, and room is left for ascribing the failure to some imperfection in the cases of cow-pox, which escaped the observation of all concerned, though it might have been ascertained by better instructed individuals. If failure takes place among those inoculated in the most approved manner, and declared by good medical authority to have had the genuine disease in the most perfect form, the necessary conclusion is, that the faculty stand in need of more accurate information.

That some such cases have occurred is admitted; but they are declared to be extremely few; and we are justly reminded that cases of repeated natural small-pox, as well as of natural small-pox after the best various inoculation, have also occurred. The rule of security is not wholly without exception in either instance. 

But, are the exceptions equally infrequent in both? This is what we are also told on very respectable authority. Such exceptions, we are informed, appear to be more numerous than they are, only because chicken-pox occurring after vaccination, has been mistaken for small-pox. There are various sorts of chicken-pox, according to the accounts given us in the writings of physicians, and all of them are mild and safe diseases compared with the small-pox. See the varying descriptions of this disease given in the works of Drs. Morton, Sauvages, Van Swieten, Burdsciu, Heberden, Cullen, and William. Some assert that there is another chicken-pox, at least an illegitimate small-pox of a severer kind, not clearly described by any of the other writers, and that the rare exceptions to the efficacy of vaccination have been cases in which this form of disease has been erroneously taken for small-pox. The general fact we have found to be, that, where parents have brought their children, apparently under small-pox, to the practitioner who had vaccinated them, and declared them safe from that disease, he has told them that it could not possibly be small-pox, and must be chicken-pox. Each party continues to retain his own opinion. The parent is certain that it was small-pox, the vaccinator that it was chicken-pox; but, since the children have got well, the contest is not worth the maintaining, and the inoculator enjoys his triumph.—And who will deny that he is entitled to this triumph, if the children always get well?—Is that the fact?—We believe it is, or at least exceptions to that most important of all results are extremely rare. However, therefore, we may in some particulars acknowledge ourselves to be in the dark regarding the minute laws of the inoculated vaccine disease. One fact must be acknowledged to be a sure preventive of all the dangers arising from small-pox. We use the word sure not in an absolute sense, but as admitting of exceptions so rare as to be totally unworthy of being taken into calculation.

The pathological principle by which the present state of our knowledge directs us to explain this fact is, that, where the infection of the small-pox comes in contact with a vaccinated constitution, it meets with a diminished susceptibility which, in most instances, obviates every tendency to the actual production of small-pox, and almost always obviates the fatal tendencies which it otherwise brings along with it.

From numerous other facts which presented themselves, we have been led lately to conclude that it affords a sure protection against the occurrence of the secondary fever, the principal danger of small-pox. We have, indeed, recently heard of an exception to this conclusion; a vaccinated person who has been known to die under secondary fever. This is not in conformity to any thing we have seen, and must be a phenomenon still more rare than the exceptions to which we have referred. As tenacious advocates for vaccination, we are obliged to declare it as our opinion, that those who agree with us in this feeling, will do much less justice to this preventive, by pronouncing all the alleged exceptions to its efficacy to be cases of chicken-pox, than by allowing that small-pox may occur after it, and by insisting rather on the comparative safety, than the great infrequency, of the disease under such circumstances.

It has sometimes been intimated that, "as the laws of nature are uniform, such exceptions are prima facie improbable; and that it is most rational to infer, when they apparently occur, that either the cow-pox, or the subsequent small-pox, is different from the corresponding disease, in the form in which the one is a preventive of the other." This may be the case. The exceptions may proceed from some cause of a powerful and decided nature. That cause may be discoverable by human inquiry; or, it may lie so deep as to mock our researches. But, let us remember that, in the present state of our knowledge, we have other facts which warrant us, from analogy, in allowing that such modifications of the animal system may not be absolute and invincible, but may exist in different degrees. Here it will be useful to revert to some well known circumstances connected with small-pox. Even a person who has already had that disease, either from casual infection or inoculation, though most frequently secured against it in
This last fact seemed to justify a remark which the author afterwards makes, and which has been subsequently animadverted on, that, "as a sure preventive of an attack of small-pox, there is a marked distinction between cow-pox and the variolous inoculation." The security afforded by the latter has had some rare exceptions; but, on this occasion, we have found it securing the system from an epidemic which attacked numbers of vaccinated persons, while many who had received the old inoculation must have been equally exposed. This is a real difference between the two inoculations in one obvious point; but is perfectly consistent with the confidence which cow-pox claims in obviating a very extensive and a very alarming danger. For the features of the different cases, and some casual suggestions for the further prosecution of the subject, as well as some marked instances of protection even from the attack of the same epidemic, we must refer to the account itself. We shall only further transcribe the summary of general practical conclusions there given, which, though differing in some instances from the belief previously entertained, are in their nature consoling.

"We are justified by the following considerations in steadily adhering to this practical conclusion, that vaccination ought still to be valued, and universally recommended."

"That by vaccination we do not positively endanger life. By the old inoculation, a disease was produced which was sometimes fatal. The danger artificially created was immediate, while that which it was intended to obviate was remote. Yet the former was comparatively so small, as to prevail on the reflecting part of the community to concur in encountering it. In the vaccine inoculation, however, we are saved all these painful calculations, because we communicate an affection attended with no danger, and the power of which over the constitution is great but silent."

"Again, allowing that the individual who has been vaccinated is equally liable to small-pox with any other, (which no person will be bold enough on the large scale to assert,) he is not liable to it in the same form as if vaccination had been omitted. This point cannot be longer doubted; and, if we proceed at first on the supposition that the small-pox succeeding vaccination is exactly equal in risk to the disease which used to be communicated in the old inoculation, it must be allowed that we gain time in the life of the individual by preferring vaccination. He is not subjected to the risk in the first instance. Years may elapse before he is exposed to the contagion of small-pox: When so exposed, he will, in most cases, be protected from it by the cow-pox; and, if at last he is attacked, he encounters a risk only equal to that which would have been earlier incurred by a previous inoculation with various matter."

"But this supposition is much less favourable than the truth. The risk even at that late period is far from being so great. The small-pox occurring in a vaccinated person is much safer than the inoculated small-pox. It has never been maintained, that the disease induced by the various inoculation was always exempt from the occurrence of secondary fever. On the contrary, some of the few who died of the inoculation, were cut off by that fever."

"The most unfavourable conclusion, therefore, that can be admitted, is, that there may be the same risk of death from small-pox after vaccination, as of deaths in the early stage of the inoculated small-pox. Thus, the risk is not only deferred to a later period, but is ultimately far inferior to what it was under the use of the best inoculation previously to the discovery of the cow-
INOCULATION.

Vaccine Inoculation.

140

Another circumstance is worthy of remark, that cow-pox, once occurring, does not give security against a future attack of the same disease. On this point different opinions have been entertained, and experiments have varied in their results. It appears, on the whole, that by one attack of cow-pox, whether casual or as the consequence of inoculation, the susceptibility to the same disease in future is only diminished. Milkers in the dairy counties are, by passing once through it, generally able to resist the contagion in future; sometimes they receive it, but always in a much milder form. It is important to keep this circumstance in mind, because some have thoughtlessly trusted to the effects of a second vaccination, after the first had for some time run its course, as a sufficient test of its efficacy. That is, they have looked for an absence of future susceptibility to vaccine influence in those cases which were worthy of dependence. The influence of a previous attack of small-pox has a similar virtue. It in a slight degree diminishes, but does not destroy the susceptibility of the constitution to cow-pox.

Some precautions are proper in conducting the vaccine inoculation. The choice of matter should be carefully attended to. It should be taken from a good vaccine vesicle, in a healthy subject, from the 5th to the 9th day of the disease. It is most certain in its effects when immediately inserted. If it is to be kept, it should be allowed to dry. Some confine it, in order to preserve it in its original moist state. They are not aware that it is subjected to much greater change by moisture than by exposure to the atmosphere. It may be kept on glass, or on the point of a lancet, or on the end of a small pointed piece of ivory. Mr. Bryce has suggested the employment of the crust, which, in its central part, contains matter dried in an early stage of the disease, and therefore perfectly pure and safe, and from which the light coloured part round the margin ought to be removed. Dried matter, in these different forms, is convenient for transportation; when about to be used, it must be moistened with water, either cold, or of a blood heat; but recent matter is always preferable, and therefore ought to be secured in every populous place, by regular weekly inoculations.

The end of the third month, when the constitution has acquired some firmness, and before it is subjected to the disadvantages of the period of teething, is the most eligible time for the operation. An adult in whom it has been neglected, it should be performed when the constitution is in its soundest state; when, for example, no cutaneous disease is present, and in females when there is no pregnancy, and when the cutanea are absent. But, when the contagion of small-pox prevails in a neighbourhood, these disadvantages must be disregarded.

With respect to the mode of insertion, the object kept in view is, to secure the contact of the matter with the cutis vera. The operator, therefore, should delicately raise the cuticle, without any effusion of blood if possible, and apply the matter to the skinned part. The method of doing this, which Mr. Bryce has found most certain of success, is, first to lay a drop of the matter on the surface, and then make several light punctures through this matter and the cuticle with the lancet. It is then to be held exposed to the air, but not to an artificial fire, till it dries, and afterwards left to itself.

The inoculator must now mark its course, whether Prognosis it is conformable to that which we have briefly stated, which is described by authors, and delineated in their plates. These last, however, afford but feeble assistance,
unless the operator has already seen the disease, as it appears in nature. The spurious cow-pox is sometimes accompanied with a severe phlegdemic ulcer, instead of a regular vesicle. It would be proper to watch the constitutional symptoms, viz. the heat of the skin, and the state of the pulse. It is better, however, to use the test invented by Mr. Bryce. If irregular eruptions appear during the progress, or after the termination of the vaccine affection, we ought to guard against cold, which might suddenly repel them, and generate a vesical affection. If daily cold ablutions have been hitherto used, these should be intermitted in such cases, and tepid bathing substituted. It is always necessary to protect the vesicle from being rubbed and broken, as such an accident destroys its efficacy. When it happens to be broken, Mr. Bryce directs that the further discharge of its contents should be prevented, and the regular course of the affection restored, by cold applications and chemical astringents. If a troublesome sore is formed at a late stage of the affection, astringents and escharotics ought to be employed, on surgical principles similar to those adopted for other ulcers presenting a similar appearance. When the vesicle is formed, but the inflamed area is too late in appearing, the part should be exposed to the heat of a fire, in order to quicken the local action, on which the regular phenomena depend. Where the local inflammation is excessive, or where a tumour is formed in the axilla, laxatives should be used, accompanied with cooling applications, or with fomentations, according to the state of the parts. If febrile symptoms should in any case be immediate in degree, they are to be alleviated by the usual antiphlogistic treatment.

The success of the practice of various inoculation, led the late Professor Home of Edinburgh to make some experiments for the inoculation of measles, which gave encouragement to other attempts of the same kind. But the disease was not found to be easily communicated in this manner. The operation was performed by means of the blood of a patient under the disease.

Repeated daring trials have even been made to inoculate the plague. These, for the most part, have either terminated in the death of the person who made himself the subject of experiment, or have failed to communicate the disease. 1NQUEST, is a term synonymous with Jury, and is frequently used in that signification in the law of Scotland.

INQUEST, or the Holy Office, is the court which takes cognizance of heresy in some countries subject to the Pope, and particularly in Spain and Portugal.

The existence of such a court proceeds upon the idea, that it is the duty of the civil magistrate, either in his own name, and by his own authority, or as the prop and the resource of the ecclesiastical power, to search after heresies, and to extirpate them. It takes for granted, likewise, the absurd and monstrous proposition, that the human understanding can be influenced and won by other means than those of information communicated, or argument proposed; and that real and conscientious discipleship can be the result of civil or political depreciations, or the infliction of corporal punishment.

In the early times, the church herself appears to have maintained a doctrine, the very opposite of that which has now been stated. As the satirist, when reduced to poverty himself, speedily perceived that poverty was no fit object of satire, so the Christians, when trembling under the fear of persecution, or expiring amidst its agonies, were not slow to discern, or backward to declare, that persecution was not the means by which true converts were to be made. Accordingly, in the Apologies which they presented to the Roman emperors, in behalf of their religion, during the first three centuries, they argue the question, and zealously maintain, that the privilege of the civil magistrate extends not farther than that of securing the peace, and promoting the welfare of the community; and that persecution for any opinion which lies hid in the understanding, whether that opinion be true or false, is not only absurd, because it is inefficacious, but unjust and cruel in the highest degree. "Non religionis est," says Tertullian, "que spondeos suciapi deflet, non vi." And the same idea is expressed by Laetantius, who lived in the fourth century. "Quis imпонat mihi," says he, "necessitatem, vel colendi quod vobis, vel quod velim, non colendi; quid jam nobis ulterius relinquatur, si eum habas quod voluntate fieri oris, libibo extorsent aliena?" And again, in another place, "Nihil iam est voluntarium quam religios, in quid, si anima sacrificandis aversus es, jam sublatam, jam nulla est." St. Hilary of Poitiers, likewise, who lived, as well as Laetantius, in the fourth century, and who, though he held the very same opinions with those who have just been quoted, is unexpectedly to be found among the saints in the Roman calendar, openly maintains the inadequacy and utter impotency of coercive measures in promoting the worship of God. "Est Deus," says he, "universitas, obsequio non egre necessario, non requirit concerns confessaum." And, addressing himself to those whose pride or whose zeal induced them to give information to the magistrate, and to prompt him to the rigorous execution of the imperial edicts, he says, "Oro vos episcopi quibusnam suffragia ad predicanium evangelium, aposcritus sanctorum? Quibus adjutis potentiis Christianum praecepta veniant, genteque ferre omnes, ex ulis ad Deum transwanderunt? Anno alium siibi assehambulant el palatium dignitatem, hymnum Deo, inorecer, inter colenas et flagella conantur? Eiusque regis Paulus Christo ecclesiis cogregatio? Nerones credo et Vespasiano patriocenentibus, invictum, in quorum nos odia confessus divinorum praedicationis efforum?" Even so late as the fifth century, St Martin, in France, (and it had been well for the world if the calendar had been filled with such saints as he,) excommunicated a bishop for accusing certain heretics to the usurper Maximin, by whose means they were put to death; adding, in the spirit of genuine Christianitv, that he looked upon them as a man that murdered, who procured the destruction of a fellow-creature.
INQUISITION.

Rise of the Inquisition.

These correct and righteous sentiments prevailed for a considerable time, and the deviations from them were slow and progressive. When the empire became Christian, it still appeared to the civil magistrate, that he was bound to support the religion adopted by the state. Hence it was that certain laws, which are yet to be found in the codes of Theodosius and Justinian, were enacted against heretics; by which they were subject to fines and confiscation of goods, and to imprisonment and banishment, according to the description of the offence, and the measure of the delinquency: with this limitation, however, in every case, that it was the peculiar province of the ecclesiastical judge to determine, whether the opinions professed were heretical or not. Hence, too, it was, that those charged with heresy by the magistrate, were usually charged with sedition or rebellion at the same time; and, whenever the punishment was capital, it was understood to be the result, not merely of inaccuracy or of perverted theology, but of a criminal opposition to the civil and political authorities. In this situation the law and the practice, respecting heresy, continued till about the year 800. The trial of the whole cause was left to the hands of the inquisitors; and, with the exception of ecclesiastical censures, it belonged to synods and councils merely to answer the question, “Is the opinion or doctrine libelled heretical or otherwise?”

During the course of the ninth, tenth, and eleventh centuries, however, the power of the ecclesiastical tribunals, and of the papacy itself, increased in a most remarkable degree. The zeal which animated the church, and the people of Europe, became fierce and ungovernable; and the crusades against the infidels in foreign parts, were equalled, in ferocious feeling and disposition at least, by those against the heretics at home. At last, in an evil hour, and under some planet of malignant aspect, and of disastrous influence, St. Dominick, (as he is called,) the father of the inquisition, arose. It was the object of this zealous, but mistaken individual, to secure the purity of the Christian faith, and to support the Papal authority, by institutions appropriated to these purposes. The trial of the accused was now placed exclusively in the hands of the ecclesiastical judicatory. The principal inquisitor was likewise the principal judge; he was responsible to no other authority than that of the Pope; and he decided, not only upon the description or quality of the propositions maintained, but finally, and without appeal, upon the guilt or innocence of the prisoner. And so complete was the revolution, achieved by the skill and the perseverance of the Romanish See, that the civil magistrate, once the sole judge in matters of heresy, was now called upon to do little else than to execute the sentences of the ecclesiastical tribunals. Strange as it may appear, this monstrous system was received by many of the nations of Europe. It found its way especially into the dominions of Spain and Portugal. The inquisitorial courts were established; and the emperor, or king, or powerful lord, themselves, trembling under the fear of excommunication, proceeded to remove from this world the unhappy individuals whom the church had pronounced to be guilty of heresy. And the example of their pagan predecessors had long ago taught them, that fire and faggot were the appropriate means by which their removal was to be accomplished.

It was by Pope Innocent IV. (A. D. 1251,) that the inquisitorial courts were introduced into Romania, Lombardy, Marca Trevigiana, and the other Italian provinces, more immediately under the authority or influence of the Holy See. About the year 1484, they were established in Spain, and in Portugal in the year 1577. In the following observations, however, we shall confine ourselves, in a great degree, to the investigation as it exists in Spain.

At the head of the inquisition in Spain, stands the inquisitor-general. This high officer is appointed, nominally, by the king, but in reality by the Pope; for the Holy See enjoys the privilege of veto upon the election of the sovereign, a privilege which on certain suitable and well-chosen occasions, it has not failed to exercise. The supreme inquisitor cannot proceed one step in the discharge of his office, till he has received the confirmation of the Pontiff. When thus elected, and thus confirmed, the inquisitor-general appoints the subordinate inquisitors; but, in this last instance, the nomination of the supreme inquisitor is subject to the review of the king. Besides the inquisitor-general there are five councillors, who have the title of apostolical inquisitors; it belongs to them to deliberate upon all affairs with the inquisitor-general; to settle disputes among the particular inquisitors; to punish the familiaris attached to the institution, and to receive appeals; and generally to act as the mouth piece of the whole inquisition. And, finally, two or three inquisitors, these have the epithet of provincials attached to their designations, and they exercise their functions, by the authority, and under the review, of the supreme inquisitorial court.

The privileges which the inquisitors enjoy are many and valuable. Each of them bears the title of lord, and are not subject to the bishops of the provinces where they reside. On the contrary, they are of the rank of religious orders to which they belong. They alone can publish the edicts against heretics; they can excommunicate, interdict, and suspend; and, except in a few cases, which are distinctly specified, they can prevent the ordinations or resident bishops, from absolving those whom they have subjected to the censure of the church. Whosoever, by himself or others, shall kill, beat, or strike, any of the inquisitors, or officials of the Holy Office, or who shall injure or damage the effects of the said inquisitors or officials, shall be delivered over to the secular power. These lordly and privileged functionaries likewise enjoy the entire rents of their benefices, without tax or impost, they are exempted from all real and personal offices, and they may form new laws, after the nature of bye-laws, against heretics, and modify the punishments at pleasure. And, last of all, they can mutually absolve, and dispense with themselves, grant indulgences to the penitent, or to those whom they shall pronounce to be so, for 20 or 40 days, as they shall think proper; and for reasons, of which they alone are the judges, they can release the companions and friars of the several inquisitors, and likewise their notaries, during the space of three whole years, from all the penances which may have been enjoined them.

When the chief inquisitor arrives in any of the provinces, he proceeds in the exercise of his functions after the following manner: In the first place, he delivers a sermon, respecting the purity of the Catholic doctrine, mode of exercising their functions in the provinces.
and exhorts the people to zealous and conscientious endeavours in the extirpation of heretical pravity. He then publishes the letters monitory, or, what is otherwise called, the edict of faith; by which all persons of whatever condition or state, clergy or laity, are commanded, under pain of excommunication, to discover to the inquisitor, "within the six or twelve days following, any person, known to them," who entertains heretical opinions, or is suspected of entertaining them. He then reads the sentence of excommunication, and makes comments upon it, and promises indulgences to those who shall favour or support him in the execution of his office. The whole ceremony is of an imposing and awful nature; and in countries where the inquisition prevails in its most fearful ascendency, it is usual, immediately after the publication of the edict, for those who are present, and especially for the magistrates of the principal cities, to engage themselves, under an oath, solemnly sworn before the crucifix and the gospels, to protect and to assist the ministers of the inquisition with all their authority and influence.

The process may begin before the inquisitorial courts: 1. By investigation, where the inquisitor summons certain individuals into his presence, and inquires into the state of the town or district where they live. 2. By accusation, where a direct charge of heresy is brought before the court against one or more persons distinctly named. 3. By denunciation, where the inquisitor is merely informed that certain heretical persons, or persons suspected of heresy, (who are likewise distinctly named), exist within the limits of his jurisdiction. This last is by far the most common mode, and it is that which the inquirers are most desirous to encourage. Informations are averagely received without any respect to the characters of the persons by whom they are given. The lowest and most worthless of the clergy and of the laity, thieves and cheats, just let loose from prison, prejudiced persons, striplants, and even children, are all allowed and invited to inform. When the information has been lodged, the following questions are usually proposed: Whether the informer knows the person suspected of heresy, and how long he has known him? Whether he is suspected of heresy, on account of his words, or on account of his actions? Whether he has said or done the things imputed to him oftener than once? and whether in jest or in earnest, and in whose company those things were said or done? The answers to these and similar questions are written down by the notary, and read over to the informer, who either subscribes his name to the document, or, if he cannot write, puts under it the mark of the cross. He is then sworn to secrecy; for secrecy, say the Catholic doctors, is the chief aim of the inquisition. His name, his personal appearance, the place of his abode, and every other circumstance respecting him, are studiously concealed by the inquisitors, lest the practice of informing should be discouraged; and having once put the court in possession of the requisite intelligence, he drops away entirely from the view, and is never again mentioned, and, if possible, is never again referred to in the whole course of the process. Thus does this odious tribunal, called by an abuse of language the Holy Office, in the very first step of its judicial procedure, afford to the most infamous the pleasure of gratification, with the certainty of concealment, and provide an opportunity for indulging there are three ways in which the inquisitors of our nature—personal malice, envy, and revenge.

After damming the informer, the inquisitor proceeds to call the witnesses. And here, too, the distinctions of character are often altogether overlooked. No previous transgression of the decalogue, no loss of reputation or of credit in society, prevents the witnesses from being listened to. Usurers, detested and abhorred, are permitted to give their evidence; "also, common gamblers, persons quite intoxicated, and not merely exhilarated by wine, stage-players and prize-fighters, apostates from religion, persons basined, bankrupts, traitors, backbiters, and spendthrifts." (Limborch, Abridg. p. 370.) And the number of the witnesses is allowed as an equivalent for their inadmissibility when they are severally considered.—We turn aside for a moment from this catalogue of infamy, in order to prevent a mistake into which our readers might naturally fall. When we speak of witnesses, in Great Britain, we almost unavoidably think of a charge regularly brought, the judges upon the bench, the jury sworn, the criminal apprehended, and in open court, the people admitted as auditors, and the whole judicial assembly feeling and acting under the assurance that they are responsible to an intelligent and watchful public, and are responsible for their proceedings. But, in the inquisitorial tribunal, where the witnesses are summoned, the party accused has not even been taken into custody. He remains in his own house, and in the bosom of his family, engaged in his ordinary occupations, and entering, it may be, into the amusements of the place where he lives; utterly ignorant of all that has been done against him, and utterly unprepared for all that is to follow. In truth, the depositions of the witnesses are viewed, rather in connection with the charge, than with the issue, and relate not so much to the guilt or the innocence of the party accused, as to the sufficiency or insufficiency of the information. Like the informer, the witnesses are sworn to secrecy; their names, and personal history, are most industriously concealed; and there are instances upon record, where brothers and sisters have given evidence against brothers and sisters, where the wife has deposed against the husband, and the husband against the wife.

The next step is the apprehension of the victim. This usually takes place in the night; and for the most part, under some favourable combination of circumstances, when the proceeding, by its suddenness, and its appalling character, is best fitted to overpower resistance, and prevent inquiry, and to multiply the occasions of secret fear. Like the tiger surveying the wild animal from the thicket, the inquisitor meditates, in silence, his horrid purpose, regards his prey with anxious vigilance, considers the whole case maturely and well, and selects his opportunity. Not the slightest hint of insecurity is given, not a suspicion is breathed, till, in the dead time of the night, a band of mounted, calmly approach the residence of the accused, and demand an entrance. To the question, In whose name is this required? the answer is "The Holy Office." In an instant the ties of nature are broken, every feeling of friendship is suppressed, and parents and children, or sisters, or brothers, with a promptitude altogether inconceivable, hasten to deliver up the victim; and the wretched individual, scarcely recovered from his surprise, and without knowing what he is accused of, is hurried away into the prisons of the Inquisition. Should conviction afterwards take place, (and the rich merchant, or substantial citizen very rarely escapes,) his property is confiscated; and the sentence of confiscation applies retrospectively, not only to the state of his apprehension, but to the time when the purity of his
faith was first suspected, or the first palpable indications of his heresy were perceived.

After a short delay, the prisoner is brought forth and examined. It is worthy of particular observation, however, that no crime is ever laid to his charge: he is never accused; for, strange as it may sound in British ears, it is the exclusive object of the inquisitor to draw from his own lips a confession of his guilt. He is first required to declare, upon oath, that he will answer, sincerely and directly, the questions which are put to him. He is then asked if he knows where he is, and whether he is aware that he is at present within the walls of the inquisition, and why it is that men are usually detained in the custody of the holy office. He is then desired to recollect himself, and to run over in his mind the events of his past life, and to search out and ascertain, whether he may not, on some occasion, have said or done some one thing or another, contrary to the purity of the Catholic faith, and the authority of the Inquisitorial Court. If he persists in maintaining his ignorance, he is informed that every degree of mercy is shewn towards those who confess, while the obstinate are treated with the utmost severity; he is soothed and threatened by turns; his offence is ascribed rather to his simplicity and the easiness of his disposition, than to any criminal purpose or unusual depravity; he is reminded of the horrors of imprisonment, its hunger, filth, and stench; and something is said about the pure air of heaven, and the blessed light of the sun. The questions are then varied in every possible way; and every art of unrighteous investigation is tried; and if, after all, he should still persist, declaring himself ignorant of any word or action that could be construed into heresy, he is told that he must be carried back to his dungeon, to aid his memory by reflection, to commune with his own heart, and to subject the resolution of a haughty spirit to the dominion of conscience.

The cells of the inquisition are square apartments, each side being about 10 feet in superficial measurement. There is usually one row of them built over another. The cells of the upper row are lighted by means of a small iron grate placed in the cell; those of the under row are sunk beneath the level of the external surface, and are perfectly dark. Each apartment has two doors, one exterior to the other. The inner one is of a massy thickness, and faced with iron, having a grate on the under part of it, and in the upper part an opening, through which his victuals and other necessaries are delivered to the prisoner. The outer door is entire, without grate or opening, and, like the inner one, is exceedingly strong. The walls are commonly about seven or eight feet in thickness. In each apartment there is placed a bed of rushes, together with two pots of water, one to wash in, and the other for drink. There is likewise a larger vessel, which is emptied every third or fourth day. The treatment of the prisoners varies according to their rank or fortune. Those who are poor have half a rial for their daily subsistence, which allowed them by the king out of this pitance, however, the provision-buyer, or dispenser, as he is called, the cook, and the jail-keeper, must all be paid; and the proportion claimed by each of these functionaries amounts to nearly one-tenth of the whole. Dr. Geddes mentions a prisoner in the Inquisition at Lisbon, who was allowed no more than three vinijcas a day, or threepence-halfpenny of English money.

The obstinate heretic is consigned to the apartments of the under row. There he sits upon his bed of rushes, in darkness, solitude, and silence, without ever seeing the face of a human creature excepting that of his keeper, or hearing the sound of any voice but his. He is forbidden to make the slightest noise, even to cough or to stir. It were a mockery to allow him the use of books; for, being shut up in total darkness, he could not peruse them. The morning, and the evening, the day, the week, and the month, pass over him, in the same stillness and seclusion. Sometimes the prisoner is doomed to spend whole years in this situation; hot and feverish, amidst the miseries proceeding from his own body, or putting alive in the accumulating filth of his apartment, which, through weakness or disease, he is unable to remove. “As liberty,” says the author of the Letters on the Inquisition, “is sweet upon any terms, and even the galleys themselves are a paradise when compared with the dreary cells of the inquisition, where every kind of rigour is put in practice which can render life a burden, without any interval, or the least alleviation, nothing is more natural than for one, confined to such a prison, to wish, with the utmost anxiety, for the next auto da fe, which, though a bitter remedy, is the only one that can afford him any prospect of relief. But even this miserable comfort is denied him. The wretch sits sighing and pining away within his gloomy dungeon in Castile, of the solemn day when he shall be permitted to behold the light of the sun, to breathe the fresh air, and cheer his eyes with the sight of his friends and relations. The long-wished-for day at length arrives; it passes away; and the unhappier individual still remains in the same doleful situation.” Sometimes, however, the strength of his noble mind is broken; and worn out by unmitigated and hopeless suffering, he believes his own consciousness of innocence, declares himself guilty, and subscribes any confession which the inquisitors may choose to put into his mouth.

There is nothing in the history of the inquisitorial procedure which has called forth such universal reprobation as the fact, that the prisoner is never confronted either with the informer or the witnesses. He is not even told who they are. If the evidence is given to him in writing, as is sometimes the case, it is prepared in such a way that he can by no means learn from it, how the information against him was communicated, or the proofs of his delinquency have been obtained. The evil of these practices was long ago perceived. In the beginning of the 16th century, the Moors and Jews residing in Spain offered 800,000 pieces of gold to Charles V., who had just succeeded his grandfather Ferdinand, King of Castile, provided he would introduce a law, ordaining that the names of the witnesses in the inquisitorial courts should be regularly published. Charles, who was only eighteen years of age, was very strongly tempted to accept the money; but Cardinal Ximenes, at that time inquisitor-general, represented to the king that irreparable injury would be done to the church if he permitted the practice, and by reminding him of his grandfather Ferdinand, surmised the Catholic, he prevailed upon him to refuse the offer. It was this same Cardinal who objected to the translation of the Scriptures into the vulgar tongue, saying, “that the books of the Old and New Testament ought to remain shut up in the three languages which God, not without the greatest mystery, had directed to be placed over the head of his dear Son as he hung upon the cross.” Cases, however, have occurred when it was necessary that the witnesses should see the prisoner, in order to ascertain his or her personal identity. But even in these cases, the business has been so conducted, that the prisoner was n
The Inquisition.

The usual method has been to introduce the prisoner into the company of several other persons in the same dress with himself, and to permit the informer, or the witnesses, to inspect the whole party, through a small opening, or crevice in the door. And though it has sometimes happened that they have mistaken the guilty individual, and made a wrong choice, even after repeated trials, yet such is the nature of these courts, and so necessary is it that informations, of whatever description, should be communicated, that those false accusers, and deliberate and perjured destroyers of the innocent and the unwary, have been allowed to escape with little more than a very gentle rebuke.

It is an unfrequent occurrence, that while the prisoner refuses to confess, and remains in his dungeon, the inquisitor affects to be displeased with his obstinacy, and condemns him to the torture. But first of all, attempts are made to frighten him in various ways. The instruments of torture are shewn him at a distance. He is led, by many windings, and through a succession of doors, into a large room, feebly lighted, where the executioner is pointed out to him, covered with a black linen garment, which reaches down to his feet, and having a long cowl of the same colour drawn over his head and face. This extraordinary figure carries in his hand an iron collar, or a whip, or some other instrument of torture, and he appears to stare in solemn stillness at the prisoner, through two small openings, which are made for that purpose in the cowl. "All this," says Constatins, "is intended to strike the miserable wretch with greater terror, when he sees himself about to be tortured by the hands of one, who thus looks like the very devil."

The degrees of torture formerly in use were five in number. They were inflicted in succession, and have been described at length by Julius Clarus. 1. The threatening of the torture. 2. The steps taken when conducting the prisoner to the place of torture. 3. The torture by stripping and binding. 4. Elevation upon the rack or pulley. 5. Squashing, or the sudden precipitation, and sudden suspension of the body. To these may be added, the iron slippers, the colt, or wooden horse, the thumb-screws, and various others. The measure of the severity is indicated by the terms in which the orders of the inquisitors are expressed. If it is said, "let the prisoner be interrogated by torture," he is merely hoisted up upon the rope, but does not undergo the squashing. If the order bears, "let him be tortured," he must undergo the squashing once, being first interrogated as he is hanging upon the cord and engine. If it is said, "let him be well tortured," he must suffer two squashings. If the expression is, "let him be severely tortured," it is understood of three squasinations, inflicted at three different times within the space of an hour. If, "very severely," it must be done with twisting, and weights suspended from the feet of the prisoner; and if, "very severely, even unto death," the criminal's life is in immediate danger. Should the prisoner, through the weakness of human nature, or the extremity of the sufferings, be forced to confess, his confession is instantly taken down by the notary; and if he adheres to it at his next examination, which commonly takes place in twenty-four hours after the infliction of the torture, and, at the same time, acknowledges his guilt, he is condemned, it is true, as a heretic upon his own confes- sion, but is represented as penitent, and restored to the bosom of the church; though not without undergoing certain punishments, more or less severe, and certain painful varieties of penance. But, should he either retract his confession, or persist in his heresy, he is delivered over to the secular power, and is burnt alive at the next auto da fe.

The punishments inflicted by the Inquisition may be regarded as of two sorts, punishments not issuing in death, and punishments which have that issue. Under the first of these heads are comprehended the ecclesiastical punishments, such as penance, excommunication, interdict, and the deprivation of clerical offices and dignities; and under this head too, are included the confessions of goods, the disinheriting of children; for no child, though himself a Catholic, can inherit the property of a father dying in heresy; the loss of all right to obedience on the part of kings and other feudal superiors; and a corresponding loss of right to the fulfilment of oaths and obligations, on the part of subjects; imprisonment in monasteries or in jails, whipping, the gallows, and the ban of the empire, or dilution. Under the second head, or that of punishments issuing in death, there are only two instances, viz. strangling at the stake, and death by fire. These instances may easily be comprehended in a short account of the "auto da fe." For the severity of the latter class of punishments, Simancas gives what is called by Limborch, "a merry reason." "We must not contend with heretics," says he, "by Scripture, as by that, our victory will be uncertain and doubtful."

In the procession of the "auto da fe," the monks of Procession the order of St. Dominic, walk first. These carry the standard of the Inquisition, bearing on the one side, the picture of Dominic himself, curiously wrought in needle-work, and on the other, the figure of the cross, between those of an olive branch and a naked sword, with the motto "justitia et mericorindia." Immediately after the Dominicans come the penitents, dressed in black coats, without sleeves, barefooted, and with wax-candles in their hands. Among these, the principal offenders wear the infamous habit called the sam-benito. Next come the penitents, who have narrowly escaped the punishment of death; and these have flames painted upon their garments or benitores, but with the points of the flames turned downwards, importing that they have been saved, "yet so as by fire." Next come the negative, and the relapsed, the wretches who are doomed to the stake; these also have flames upon their habits, but pointing upward. After the negative and the relapsed, come the guilty and impenitent, or those who may have been convicted of heresy, and who persist in it; and these, besides the flames pointing upwards, have "their picture (drawn for that purpose a few days before) upon their breasts, with dogs, serpents, and devils, all with open mouths, painted about it." This part of the procession is closed by a number of individuals carrying the figures of those who have died in heresy, or large chests, painted black, and marked with serpents and devils, containing their bones dug out of the grave, in order that they may be reduced to ashes. A troop of familiars on horseback follow the prisoners; and after these come the subordinate inquisitors, and other functionaries of the Holy Office, upon mules; and, last of all, comes the Inquisitor-General himself, in a rich dress, mounted upon a white horse, and attended by all the nobility who are

The Inquisition.

**INSANITY.** This word ought, from its etymology, to signify “want of soundness,” or “want of health.” It is applied, in the English language, to denote an unsound state of the mental powers. It is generally used as synonymous with “mentual derangement.” But it is more proper to consider it as including a greater extent of malady, by comprehending cases in which the mental powers are in themselves deficient, as well as those in which they are disordered.

It is a matter of great importance to fix the definition of insanity, and characters of insanity with such precision, as to render the practical application of just principles on the subject a matter of certainty. The imputation of insanity to any individual brings after it the most serious consequences; as it subjects him, in the best regulated communities, to the loss of the common privileges of a man and a citizen; and, in certain states of society, and during the prevalence of certain opinions, is followed by subjection to the lowest degradation, to utter contempt, to horror, and even to cruelty. As soon as a man has been declared insane, he has too often happened that he has not only been excluded from the common enjoyments of society, but cut off from all that consideration and tenderness by which comfort is preserved, and has been committed to the custody of persons who had no interest in his recovery or welfare, and from whom no duteeful line of conduct was exacted or expected. The rash application of such an imputation is an event the possibility of which, under these circumstances, cannot be thought of without horror. But, even under the prevalence of the most humane principles, and the most considerate and discriminating treatment of the different descriptions of insane subjects, the question does not lose its importance, When ought any individual to be pronounced insane?

Human minds are so differently constituted; their intellectual excellencies and defects are so often and so strangely blended, and contrasts so striking present themselves in the mental features of the same individuals; the gradations of mental qualities and mental states are likewise so numerous, and difficult to separate from one another, that this question is as hard as it is momentous to solve.

Practical distinctions, with a view to legal proceedings, therefore, are very properly regulated by the effects which the mental character and state produce on those parts of conduct which are essential to man as a member of society, and the safety and suitableness of allowing him to remain at large, and manage his own property and interests. This is more kept in view than the minute analysis of the mode in which the mental operations are conducted. It is a common adage, that the chief difference between a fool and a wise man is, that the wise man has sufficient art to conceal his deficiencies. We only descend a grade lower, when we distinguish an insane from a sane mind, in describing what we commonly call a fool in contradistinction to a wise man. It is often a flat and total loss of a view of his relationship to other men, in addition to those follies which are common to him with many other persons, that decides a man to be insane.

It often appears an important point, when an atrocious action has been perpetrated, to determine whether it should be ascribed to insanity or to crime. But, it may be observed, that every case in which this point

---

Insanity. 

is questionable, is ultimately determined by utility, and the influence of example. Minds so constituted by nature, or distorted by disease, that the common motives of mankind do not reach them, are very different from those in whom an obtuseness to humanity, justice, and rational fear, is the direct effect of a depraved self-indulgence. In the former, common motives and common actions are, in this respect, entirely fortuitous; whereas the latter are cases by the punishment of which a numerous description of persons are restrained from criminal actions. To prevent crime is the object of criminal legislation, and not to gratify, by the infliction of pain, that just antipathy which the virtuous entertain to moral evil. We by no means assert that this consideration is the sole foundation of the distinctions to be made between the different sources of human actions, and that accountableness has no meaning in itself. In the greater number of cases, the difference between voluntary and involuntary conduct is broadly marked. But wherever a difficulty exists, the principles of utility, and a reference to the ultimate consequences of our decision on the safety of social life, afford the surest aid. — Wherever a due degree of attention has been paid to the aberrations of the human mind, by the parties called on to give their decision before a man is to be treated as insane, and whereas the whole proceedings are subjected to a fair degree of publicity, we have little to apprehend, in an intelligent state of society, from the mere difficulty of the subject. It is from incomprehensibility, rudeness, the toleration of low mercenary motives, the avoidance of a duty foolishly reckoned disagreeable, the unnatural combinations which the false pride of some leads them to form with others who are actuated by the worst motives to cultivate a policy of unmanly concealment, that the most lamentable abuses on the subject of insanity have derived their origin. But it is one of the most animating features of the present age, to find the general mind rising superior to such negligence and mistake. We may probably hail this improvement as a precursor of a sounder moral principle. On the other hand, it is an imbecility exactly similar to that of natural idiots, has often occurred, from various causes, in persons who had previously been in full possession of their faculties. It is only a prevailing, it is not an universal fact, that congenital insanity assumes the form of idiocy, and supervening insanity that to which we give the name of madness.

To trace the connection between deficiencies of mind and defects or disorders of organization, is not an easy task. Nature invites us to it by some prevailing coincidences; but, when we trace these down to their minutiae, she leaves us in the midst of such mere conjecture and uncertainty, that we find it difficult to determine the point at which our researches become unwavering. Idiots are evidently distinguished from other persons by a peculiarity in the appearance of the head. Most commonly the head is of diminutive size, and that part of the brain which lies between the forehead and the vertex, is small in quantity. At other times, the back part of the head appears deficient; the boundary of the occiput is a vertical line in continuity with that of the cervix, and the anterior part of the head is towering and heavy. Some who have professed to prosecute the subject extensively have told us that these were cases in which the ventricles of the brain were distended with a serous secretion, and the cerebral substance both deficient in quantity, and subjected to all the disadvantages arising from dropsical oppression and disor-
Insanity. This has been declared to be universally the case with idiots whose heads either exhibited this particular shape, or were preternaturally large. These observations have not yet been sufficiently extensive, and attested by a sufficient number of observers, to form a part of the ascertained doctrines of science. This is no derogation from the credit due to the observations of those who have undertaken them; who, though they may not be trusted as superior to the influence which enthusiasm sometimes exercises over the power of observation, deserve praise for their devotedness to the object, and will be entitled to more lasting honour if even a few of their positions shall be ultimately established. Casts of the heads of idiots whose cases are minutely described, and whose brains have been dissected after death, if multiplied and well authenticated in different countries, cannot, fail ultimately to throw much light on the nervous system, and its connection with the manifestations of the mind. Yet it is possible that the conclusions obtained may widely differ from any that have been hitherto anticipated.

The chief characteristic about the head that is strictly universal, consists in the manner of holding and moving it, and thus, like other points of pure physiognomy, resolves itself into the habits of the moving powers. Yet we cannot deny that there is a deficiency of organization more strictly radical than this, which careful inquiry may be afterwards able in some measure to trace, though we should not indulge the hope that the subject is capable of being thoroughly explored.

The treatment of idiots is not a matter of great difficulty. The duties of humanity are generally in these cases simple, and the events to be expected either from the course of nature, from accident, or from any treatment, admit of very little variety.

The case is far otherwise with those forms of insanity which are not congenital. To such forms of it, therefore, our chief attention is due.

Here, again, science finds herself cramped and embarrassed wherever the love of an easy and brief accuracy calls on her for a definition, or demands mention to be made of any universal characteristic which is essential to insanity.

Insanity, as thus applied, includes melancholy and madness. The symptoms of melancholy, however, often alternate with those ascribed to madness, and madness often ends in settled melancholy. When melancholy exists separately, it is found in various degrees. Few persons are at all times exempt from it. It is that state which disappointment and external disadvantages have a uniform tendency to produce. It is when comparatively permanent, and affecting a man's feelings towards every object, that we call the disease hypochondria, or, in common language, "habitual discouragement." "Low spirits," and the subsequent "indifference" tending to that abolition of feeling and of interest which we call melancholia, are greater degrees of the same mental disease. When symptoms of melancholy exist separately from those of mania, the individual is disposed to decline the common affairs of life in a greater degree than he appears to be unfitted for them; no coercion or confinement is called for; no mischief is to be dreaded, excepting that in some cases a tendency to suicide may be suspected to be present, or that mania may be apprehended as its ultimate consequence.

Our further delineations and remarks shall be confined to mania, by far the most important branch of the subject of insanity.

It is in cases of mania, that the perplexities to which we have already alluded in forming our decisions principally occur.

The difference between the state of the thoughts in manias and in others is not easily described or defined; but it is judiciously observed by Cullen, that "it always seems in the form of false judgments, and irresistible actions; sometimes confused, sometimes separate. Aberration of any sensation or intellectual power is so incident to all men, that it cannot constitute insanity. Hence some have made this distinction, that in the insane the aberrations are totally unperceived. Even this, however, fails to afford us a sure diagnostic. Maniacal aberrations of judgment seem only a greater degree, and a more unaccountable form of that ignorance of ourselves, our motives, our character, and the relations in which we stand to others, which abounds among mankind. And with regard to the irresistible aberrations of feeling of the maniac, he is in many cases very far from being unconscious of their existence and influence. Perhaps the following definition, although it does not present to the mind the striking image of madness, will more nearly designate all cases of this malady than any other that has been given: "A continued impetuosity of thought, which totally unites a man for judging and acting with the composure requisite for the maintenance of the social relations of life." Yet this definition will only apply with propriety, in consequence of the emphasis to be laid on the word "totally." We must profess our dissatisfaction with all definitions. Words are only aids to our minds in giving precision to our observations on phenomena which must be presented to our actual view before a conception of them can be formed; and this is one of those subjects, on which the words must be numerous, and extend to the length of a historical description, before they can communicate precise information. Even then their deficiency is apparent; and, when we are limited to a short compass, as in the present article, we rather hope to present instructive sketches, than an entire view of this important subject, the study of which is worthy of being much better cultivated. The impetuosity of mania appears under two leading forms, furor and delirium. Furor consists in an extreme irascibility, and an invincible propensity to commit indelent or atrocious actions. It is considered as a disease of the will. Delirium consists in an extreme hurry of imagination, sometimes attended with a false perception of objects as present which are not, and always depriving the patient of those just notions of the relations of things around him which he entertains in a state of health. It is, therefore, considered as a symptom of disease in the intellectual powers. Impetuosity, however, is a characteristic in which it agrees with furor. A diseased inclination attaches the patient to those rambling thoughts which derange the operations of his judgment.

Mania has seldom been known to attack any person before the age of puberty, after which period all ages attack are subject to it. It is sometimes preceded by deep melancholy, or by a slight lowness of spirits. In persons addicted to intemperate drinking, the approach is sometimes indicated by an increase in the extravagance of conduct attending their excesses. The most general mark of decided mania is a total change of feeling towards connections and acquaintances, indicated by a suspiciousness, and a violent hatred towards those persons who at other times are objects of affection and confidence. Very often the patient shews remarkable proofs of penetrating sagacity, brilliant wit, and an im-
Mania. 

posing eloquence. He seems to understand better than at other times what is going forward around him, but gives an erroneous and generally a malignant construction to every transaction. There have been cases in which he has felt a strong inclination to assault, and even to murder every person that came in his way, although he could converse rationally, and deplore those unguarded inclinations by which he felt himself so inevitably swayed. Sometimes there is an inclination to suicide, seeming to arise not so much from a sense of unhappiness, as from a mere tendency to extravagance. The patient is so prone to novelty, and to break away from every object, regardless of consequences, as to grasp eagerly at any opportunity that may be given him, of throwing himself from a dangerous height. Here we have only a greater degree of those nervous feelings which are experienced by some persons in apparent health and soundness of mind. We have known a man of the greatest respectability, who acknowledged that, whenever he passed a particular bridge, he felt a slight inclination to throw himself over, accompanied with a slight dread that this inclination might hurry him away.

The delirious ravings which characterise mania in its perfect form, are as various as the characters and ideas of individuals. Sometimes they are confined to one object, which absorbs an inordinate degree of interest; but most generally there is a false judgment on every subject that occurs.

The cunning of maniacs has often been remarked, as appearing in the uncommon address with which they accomplish their whimsical purposes, and the pertinent questions which they propose in order to obtain satisfactory answers, instead of the evasions practised by an inexperienced attendant. A patient in the lunatic asylum of Manchester, when the writer of this article attended that institution, was found one morning to have lost his ear, and, when interrogated about the instrument with which he had thus mutilated himself, he first made a great mystery of it, and then boasted of his address in abstracting a button from his neighbour's coat, sharpening it on a stone, and cutting off his ear with it before any person could observe him. In this instance, we may remark the horrid contrast between the unnatural object which the patient had in view, and the skill which he employed to accomplish it. A similar contrast under a variety of forms is of frequent occurrence. The impressions which objects make on the patient's mind are often extravagant, while the reasons which he establishes on these impressions are close and strong.

Mania is often subject to intermissions, during which the patient appears as well as previous to the attack, except that, not being engaged in his usual occupations, and being sensible of the existing tendency to disease, he shews less of the regular interest which he used to take in surrounding objects, and a degree of shyness towards those who address him. It is currently supposed by persons not intimately acquainted with the phenomena of mental disease, that the lucid interval must be the most horrid of all possible states of mind. They conceive that the temporary return of reason, bringing to the patient's mind a view of his deplorable malady, must continually shock him with much greater violence, than it can affect those who imagine to themselves the same disease in others. This, however, is a mistake. The lucid interval brings with it an exercise of reason less indeed to be depended on, but in some respects more correct than it is found in the generality of persons who never laboured under the disease. The patient becomes resigned to his situation, and feels the propriety of not suffering the thought of it to distress him. Were it not for this reflection, which his experience has taught him, he could not be supposed that mania would have any intermission, or ever terminate in recovery. The sensibility, besides, is often exhausted to such a degree, by the perplexity suffered previous to the attack, that circumstances really gloomy have much less influence than formerly in depressing the mind.

The patient also experiences a secret delight in the return of sound impressions, and knows that the best way of cherishing them is to avoid every afflicting thought. It is seldom that mania returns at regular periods. Of two hundred patients under the care of M. Pinel, in the Bicêtre of Paris, only six were of this description, and their periods were different from one another.

A violent attack of maniacal excitement is sometimes terminated by a sudden debility, in which the patient is speedily carried off. Sometimes persons who have been for a long time in a maniacal state, recover composure of intellect, which continues for a year or two without any relapse; but afterwards lose the whole energy of their constitution, and are cut off by that species of decay which is called atrophy.

Very often it happens that a patient, after being for some time recovered from mania, is cut off by an apoplectic attack.—It is very common for the disease to degenerate into a chronic idiotism, which continues for life.

The corporeal phenomena of mania are of less uniformity than the mental; but, when they occur, they throw light on the existing state of the constitution, and attention to them becomes necessary in practice. Want of sleep is the most common symptom of this kind. An apparent increase of strength is also very frequent. Fever, constipation, dryness of the skin, and increased heat in the head, are frequent symptoms. It has been supposed, that patients under mania are less sensible to external cold than healthy subjects. This has been denied by Mr. Haslam; and probably will only apply to this disease in its acute state, and its earliest stages.

The prognosis of mania is in general difficult. The earlier in life that it comes on after puberty, we, ceteris paribus, have better hopes of a recovery. The previous dispositions of the patient are worthy of our attention. In persons naturally shy, and easily discouraged, the prognosis, though not rendered decidedly bad, is rather less favourable than in others. Mania accompanied with mirth, is less hurtful to the health, and less obstinate than that which is marked by horror and distress.

When this affection has succeeded to a long continued religious melancholy, we have little expectation of a perfect cure, particularly if the patient has been strongly attached to discouraging opinions.

Where the patient's turn of mind has been previously characterized by singularities, and still more where his whole conduct has indicated a want of common prudence and feeling, an attack of mania, though apparently cured, leaves behind it a character of increased folly. In persons of ingenious dispositions it is sometimes followed by a character of greater modesty; but the morbid sensibility is increased in proportion to the increase of external prudence, and the patient runs a risk of being carried off by apoplexy.

The disease becomes less hopeful in proportion to the length of its continuance. Hence, in some institu-
INSANITY.

Causes of madness.

Mania has always been considered as an hereditary disease. This opinion is certainly founded in truth. When we find the features and expression of the countenance so often exactly copied from the parents, we have good reason to conclude that the constitution and character which predispose the constitution to mania are communicated in the same manner. The facts are also well confirmed in this particular disease by the experience of mankind. We cannot, however, ascribe so much influence to this cause as is generally done. Other causes contribute to the repetition of it in the same family, independently of communication from the parents. It has been sometimes maintained, that the present frequency of mania in this country has proceeded from the intermarriages of persons of sound constitutions with those who have laboured under this hereditary disposition: but we have no reason to suppose that, at the time when mania became so prevalent, such intermarriages were more frequent than formerly, or that these are now more common in proportion to the cases of mania that exist.

Marks of a predisposition.

The predisposition to mania is marked by peculiar sensibility, accompanied with a disposition in the person to conceal the manner in which he is affected; and sometimes by absence of mind. A determination to the head, which predisposes to apoplexy, is also a predisposing cause of mania, and probably terminates in the one disease or in the other, according to the conjoint operation of other causes. The same thing may be said of that tendency to inflammation in the brain, which is the predisposing cause of phrenitis. Madness is well known to be sometimes occasioned by organic injuries in the head.

Occasional cause.

Excessive sensuality, and intemperance in the use of intoxicating liquors, or other narcotics, are frequent causes of this disease. Their immediate operation is to produce a temporary state nearly allied to it; and, where this is frequently repeated, the tendency becomes at last rivetted in the system. The suppression of various secretions is numbered among the causes of mania, as obstructions of the menses, checks given to the perspiration, and the drying up of a long continued discharge from scrophulous sores. That disturbance of all the functions which is incident to the periperal state, is a very frequent cause of mania. When we consider the extreme delicacy of many females in the higher and middling rank of society, we cannot be surprised at any effect that follows the shock which all their sensations must sustain in childbirth.

Whether is madness owing most to the mind or the body?

One question has been agitated as of the greatest importance; whether the disease is ever strictly mental, or is always dependent on faults or peculiarities or injuries of organization? The degree of importance attached to this question is in some measure to be regulated by the meaning which we attach to terms. It is evident that it might be so managed as to involve the whole doctrines which relate to the nature of matter and of mind, and might thus lead us into the most unsatisfactory regions of metaphysical discussion. This must be avoided when we are in quest of real information. In so far as the question is practically useful, it may be resolved into this, Whether is insanity, supervening from the application of a mental cause, without any apparent bodily defect or ailment, always the effect of this cause only, or in conjunction with some fixed and very particular predisposition in the organs by which the powers of the mind operate? We do not adopt the latter part of this alternative. We grant, indeed, that insanity owes its origin to certain relations which the external cause has with the state of the subject operated on. But we contend that the predisposition is most commonly founded in a delicacy which is very general among men; that the increase of this delicacy in any individual is chiefly owing to a series of external impressions, and that even the organic peculiarities which are the most strongly marked are the consequences of such impressions, either communicated to the individual or to his progenitors. This susceptibility, which in one nation produces insanity, may in another appear to be absent, from being operated on in such a form as prevents variety of mental exercise, and renders the individual entirely the creature of a limited set of habits; and it is questionable whether any abrupt attempts to change the habits of an individual thus situated would not readily induce insanity. They would certainly occasion unhappiness, or probably death.

If insanity were not the effect, he would probably owe this exemption to the want of that sort of mental employment which exists in those tribes among which that malady is common. Very few persons, perhaps none, are exempt from the symptoms of madness during particular moments of their lives. Dreaming is a state of madness. Reverie, or vague musing, is nearly allied to it. The irregularity and imbecility of thought so often experienced while a person disposes himself for sleep is a state which every one understands, and which, if it were perpetual, would constitute madness. The universal liability of mankind to this state shows that the weaknesses which lead to madness may be regarded as radically universal, and that external circumstances operating on the senses and intellectual powers, and through these on the material organs which lie hid under our view, are by far the most efficient causes of the appearance of this malady.

The mental causes which evidently occasion madness are, restless ambition, jealous love, and frequent or severe disappointments. Harassing changes are well known to be unfavourable to soundness of mind. It has been said that a sudden change of fortune from low to high has occasioned madness more frequently than a change from high to low. This was remarked in the mental effects of the celebrated mercantile speculation called the South Sea scheme, which gave occasion to numerous sudden changes of both kinds. Reverses of fortune are particularly apt to affect persons destitute of all taste for rational occupation, to whom wealth and its attendant honours form the whole interest of existence. The dreadful reverses which took place in France in the course of the revolution, formed a fruitful source of madness; some interesting cases of this sort are described in the treatise of Pinel.

The effect of affronts is often to produce mania in persons acutely sensible to the treatment which they
receive from others. Some have been suddenly seized with this disease in its most dreadful form, immediately after being made the objects of a torrent of ridicule from their companions. This effect often follows a long course of ill treatment in those natives of the East who live in the service of harsh masters. They bear it long with seeming patience, but at last they are suddenly infuriated to such an extreme degree, as to lay hold of a murderous weapon, with which they perpetrate as many outrages as they can, with the certain prospect of terminating their career by an immediate violent death. This is commonly called “running a muck.” A person seen in such a state unfortunately excites no commiseration, but is pursued and dispatched as speedily as possible.

The indulgence of anger, whether secret or open, often leads to mania. Moralists define anger to be “a short madness,” and madness we sometimes know to be nothing more than a lengthened anger. The case of mania which at first sight appeared to the author of this article the worst he had ever seen, was that of a woman in the cells of the Manchester workhouse, whom the mere sight of her attendants always roused to the utmost extravagance of passion. She loudly accused every person who came near her of the most shocking crimes, denounced every sort of threatening against them, and went over their features and dress, in order to turn every part of them into the most poignant ridicule. All this was done with a rapidity which no interposition of others could interrupt; yet in no one instance did this woman discover any erroneous judgment, farther than what is incident to any irascible person during a fit of displeasure.

Sometimes madness arises from a thoughtlessness concerning a person’s own deficiencies in prudence and conduct, which he gradually magnifies, till he imagines that he has been guilty of the worst crimes, and that the most dreadful punishment awaits him. To this succeed many other chimerical terrors, and every kind of extravagance, both of imagination and of will.

Gloomy notions in religion have proved a frequent cause of madness. The rational friends of religion take care to represent it as benignant in its tendency; but time and experience have removed from the present, it was customary to array it in the most gloomy colours, and to represent the supreme object of adoration as surrounded with nothing but infinite terrors, and his scanty dispensations of mercy as only accessible through a system of unintelligible metaphysics, so difficult in its practical application, as to leave anxiety, terror, and despondency, predominant in the mind of the worshipper. The mental devastation which this mode of thinking produced was great. The dread of unavoidable evils drove many to madness of the worst kind, which very often terminated in suicide. Although this system is now exploded, or its consequences carefully averted, still that enthusiastic imagery, which is often exhibited to the minds of ignorant persons, has occasionally the effect of deranging their intellects. These agitations, artfully excited, which are ascribed to the conflicting agency of a good and an evil spirit, divert the mind from the acknowledgment of natural causes; after which no principle can be established for stopping the career of false imagination; and, unless the balance of reason is in some degree maintained by the general influence of external objects, a person thus deluded runs every risk of madness.

Infidelity, or the renunciation of religious sentiments, has also produced in this respect its victims. Pain has sometimes been taken inhumanly to desolate the hopes which religion has inspired; and, at the same time, to inflate the mind with the expectation of much happiness from the indulgence of an unguarded expansion of thought, and of all the joys of sensual pleasure. On such principles, hopes of a new and happy state of society have been erected. The miserable, gloomy, and unconsolable disappointment, which were the unavoidable result of such a system, have been keenly felt in proportion to the hopes excited. To this cause must undoubtedly be ascribed much of the madness which occurred with uncommon frequency in France during the revolution.

A tendency to mania may be promoted in a certain state of society, by the prevalence of political and moral liberty, accompanied with a general style of thought marked with a spirit of exaggeration and conflict, and a propensity to take an inordinate interest in particular objects. In this way the increasing frequency of the complaint in Britain is accounted for. This prevailing spirit extends not merely to religion and politics, but to literature and to morals. The production of strong impressions is regarded as the most important aim of literature, while adjustment and propriety are considered as safely left to the unaided operation of private thoughts; and the distraction which is thus generated is not foreseen. Even morality has been outraged in a fantastic manner. In the most sober circles, virtue is too often cultivated rather as a passion than an intelligent perception of what is right; and an aversion to vice appears in the form of a strong sensation, rather than a masterly and well-guarded prudence. Among the more ostentatious circles, prudence is confounded with selfishness; and a thoughtless devotedness is plausibly represented as generosity. Among some of the moralists of modern times, moderation is treated as a word destitute of any conceivable meaning, except when synonymous with indifference. Every thing that passes under that name has been stigmatized as the death of the mind; while ambition has been extolled as the only legitimate symptom of activity. The whole of the moral composure which formed the object of the stoical school is represented as an unnatural apathy. By these extravagances, instead of being encouraged in cultivating the happiness which belongs to a regular employment of its powers, is hurried abruptly from sensitive pleasure and pampered imaginations to the wailings of listless sorrow, or that agitating discontent which generates gloom in private life, and clamour in public. In private economy, the transition from distressing want to ostentation leaves but little scope for a region of leisurely enjoyment. A taste for new pleasures too quickly verges into the creation of additional necessities, and becomes a source of unhappiness; and the love of order itself, by becoming fastidious, fatigues itself with the maintenance of plans pregnant with anxiety and fragility. Alienation between persons in different situations in life is connected with the spirit thus fostered, and is promoted by the want of a steady well-understood plan for facilitating social intercourse on terms productive of mutual benefit, and consistent with universal convenience. In so far as important general opinions are concerned, perhaps it is in the nature of things, that, where differences of profession are treated with mutual toleration, a period of mental warfare should precede that of sound liberality; and that the road to the happiest state of the general mind, should only be found by travelling among precipes and thickets, in which many are exposed to trials too severe for human weakness. The influence of these circumstances on the
production of madness is disguised by the great plausibility of the hyperbolical spirit; but it ought to be recollected that this plausibility throws a lustre on the manners and expressions of many individuals till the very instant in which their startling aberrations disclose the matured existence of the malady which has been all along in a train of preparation.

The last mental cause of madness which we shall mention is the principle of involuntary imitation, operating by the frequent sight of persons in similar circumstances. That this has some influence we may infer from the dread which many individuals have of entering a madhouse. That principle which leads us, even against our inclination, to adopt feelings, and repeat motions which make a strong impression on our senses, is very strong in all men. The same principle which makes a panic, (when once begun,) to spread rapidly through an army, which gives the pathos of the orator, and the performances of the tragedian, a simultaneous power over the whole of their respective audiences, and which has sometimes spread convulsions and enthusiastic visions among large congregations, exerts a similar influence in the production of nervous diseases. In hysteria and epilepsy, the effect is well known. It is not, indeed, so frequently nor so quickly produced in cases of insanity, because this disease, in its decided forms, is more distant from the ordinary state of any sane mind than these casual motions.

On this principle assisting the hereditary disposition, the repetition of mania in the same family may be partly accounted for. People think with particular frequency and seriousness of any glaring mental aberrations that affect their near connections. It has sometimes happened that the parent of a person who has become deranged has acknowledged that he felt an apprehension of falling immediately into a similar state. When the mind is weakened by sorrow, it is more easily operated on by sympathetic imitation; and the influence of this principle would be more frequently seen than it is, were it not counterbalanced by those efforts to maintain fortitude, which are dictated by a sense of the necessity of exertion for diminishing the evils with which a family is afflicted. Even those who have had relations whom they had never seen, who were subject to mania, especially if they died under the disease, must, if they know the fact, be led to think at times of that part of their family history, and certain expressions of countenance and manner, arising from such circumstances, may be communicated from one relation to another, and may thus contribute to cherish a diseased train of feeling tending to mania. We often find two or more individuals in a family becoming deranged at the same time. This we can attribute only to the influence which the progress of the morbid feelings of each has produced upon the other.

Physicians sometimes differ in their treatment of mania, according to their opinions regarding the comparative influence of bodily and of mental causes. Those who have supposed that some sort of organic fault is always the cause of mania, and that the apparent causes of it are merely occurrences slightly contributing to develop the disease, place their chief dependence on the resources of the Materia Medica; they trust to bloodletting, blistering, purging, antispasmodics, and the application of cold. This branch of the subject must be allowed to be of great importance; but for the details we refer to our article Medicine.

We confine ourselves under the present article to the moral treatment, or general management. It is well known that, even after the diseased state has been corrected, and the symptoms alleviated by the judicious use of medicine, a slight occurrence tending to irritate the mind is sufficient to destroy in one moment all the benefit produced, and to give rise to an immediate increase of violence in the symptoms. Moral circumstances must be attended to from the very beginning. The first and most important step is, to remove the change of patient from his own home, and from all the objects to which he has been accustomed to see. His false notions and harrowing impressions are associated in his mind with the objects exposed to his senses during the approach of the disease. His relations have become to him, in the first place, stale and uninteresting, and afterwards causes of angry irritation. The places where he has been accustomed to feel perplexity of thought cannot be seen without in some measure reviving it. It can seldom be expected, that in a private family individuals are to be found qualified for so difficult a charge as the care of a maniac. The most favourable situation is a retirement, where the patient will be surrounded by objects which have a composing influence. It is seldom, and only in the most violent form of the disease, that confinement in a dark room is advisable. In ordinary cases, the darkness of night brings with it an increase in the symptoms. The patient should, even for some time after he is apparently well, be kept at a distance from his friends. His importunities, and those of his connections, for a premature restoration to his family, ought to be firmly resisted till his recovery is well established. From the too frequent neglect of this precaution, many violent relapses take place. Dr. Cullen judiciously recommends that, where the patient cannot be removed, the furniture of his room should be changed. In the Bicêtre at Paris, religious mania was often increased by the presence of the emblems of the Catholic worship, and it was made a serious question whether or not all such emblems ought to be removed from the hospital. The propriety of removing all such objects ought not to be doubted.

A patient might be hurt by an insult offered to his opinions, but not by a step purely negative in its nature.

Harsh measures, compared with those of a milder kind, are harsh and mild treatment.

Tyranical principles, aided by the same passion for the extraordinary which in former ages led to a harsh treatment of almost all diseases, have been in some measure the causes of the cruel severities often practised with this description of patients. They have, for the most part, had the effect of inflaming and irritating the disease. In more enlightened times, iron fetters, tight ropes, cruel floggings, and blows, have given place to the use of the strait waistcoat, which is at once milder and more efficacious. There is no doubt, however, that a mild treatment has sometimes failed, or even appeared to be hurtful. Some writers, on comparing these facts, have contended themselves with observing, that harsh or mild measures ought to be employed according to the state of the patient, and our experience of the effect of each method upon him. We must, however, beware of suffering a mixed practice of this sort to degenerate into an ambiguous and inmethodical empiricism. The principle which we should follow is, to practise uniform decision without harshness or indignity, and to allow the patient, within a certain range, a liberal degree of freedom without trifling. I
the management of a lunatic, talents of the same sort are required as in conducting the moral education of children, or the political affairs of nations. The general principles to be adopted are the same, and the difference in their application is less in reality than in appearance. A keeper should show the patient that he is so completely in his power as to render all resistance on his part vain, and at the same time convince him that this power is not to be exercised under the influence of passion or caprice; that it is to be confined to salutary restraint, and not extended to the infliction of severities. The boundaries of indulgence ought, however, to be clearly understood; the patient's requests, when improper, must be refused with a mild firmness, and no vague promises held out to him which are not to be fulfilled. The mild character of the treatment must always appear to be that in which the patient's attendants take the greatest pleasure.

The plan of treatment, with respect to severity or mildness, requires to be adapted to the former habits of the patient. A man who has lived in a polished society, in which deference has been shown to his feelings, will be greatly injured by a degree of harshness which would be productive of no harm to a person who has been used to submit tamely to severities. As instances of the latter, Pinel particularizes the negroes of Jamaica; but it may be doubted, considering the former history of a great part of these individuals, how far their minds are subdued to their situation. In the Russian boor, who is accustomed to feel the master's lash as a necessary incitement to his daily labours, we probably have a better example of a person to whom, in a state of mania, a certain degree of harshness would be of service. If a person of these habits were to be treated with all the mildness that is used in a French lunatic asylum, he would be rendered unfit for returning to his former situation. Universal experience shews the danger of habituating any person for a time to indulgences which cannot be secured to him for the remainder of his life.

Any sort of reasoning with a maniacal patient ought to be very sparingly employed. Pinel mentions a case of religious mania, which he attempted to cure by reasoning the patient out of his irrational opinions; but the attempt only seemed to serve him to the most furious indignation against the impiety of the person who disputed the sacredness of his favourite doctrines. Reasoning even on more indifferent affairs only gives the patient an opportunity to gratify his vanity by displaying his eloquence in reply. Our object is, not to improve his accuracy in the application of language, but to restore that solidity of thought which is independent of the use of words, and that mental composure which no words can represent. Verbal reasoning shews too much haste to accomplish the recovery of our patient. Silent and steady means, accompanied with frankness, and free from all sudden excitement of turn and twist, will enable us, by much aurer steps, to conduct a favourable case to a complete recovery.

Deception to be avoided.

Pinel and others mention instances in which a little fraud has been resorted to with marked advantage: it is not, however, void of danger. If the fraud is suspected, it not only loses its effect, but excites the patient's indignation. Instances have happened in which, after an apparent recovery produced in this manner, an explanation of the deception has created reflections which have been followed by a complete relapse. Perhaps this is less liable to occur with the French than with the British; as the former, setting more value on the politeness of the moment, and less on plain dealing, are probably less affected by a slight deception where no other serious consequences are produced by it.

Regular labour is often of great use in assisting the utility of recovery of maniacs; but in public establishments in labour, this country, a general provision for that object has not been made. It requires very exact precautions to find employment for such as are fit for it, and at the same time to prevent any of the patients from having access to tools of which they might make a dangerous use. For this purpose, the separation of the patients, according to a judicious classification of their cases, is indispensable; and provision will undoubtedly be made for this in the arrangement of all new public establishments for the treatment of the insane.

When the high symptoms of mania have subsided, it will be proper to allow the patient to see a little of society; hence those who are in a mild or convalescent state in an hospital are allowed to associate together, and those who are further advanced associate with the servants and superintendents of the house. There are certain states in which an opportunity may be allowed for the return of the former sympathies of life, by gradually permitting the patient to receive frequent visits from his near relations. One instance in which sympathy operated in the cells of the Manchester Workhouse, forcibly struck the writer of this article as one of those fortunate occurrences which it is not easy to repeat by any contrivance. A maniac was visited by his wife and two children, one of whom gave him an apple: this circumstance awakened his sensibility, and made him melt into tears. The scene was observed by the worst patient in the house, the furious woman who has been already mentioned; her ferocity was immediately subdued, and she wept along with that unfortunate parent, recollecting, no doubt, the children whom she herself left at home.

From that day she made speedy advances to a state of perfect composure, and in a few weeks was dismissed cured. In this instance it was apparent that, though the incident was in itself fortunate, it was equally fortunate that she had not, in the first instance, seen any of her own children. In that case the association of ideas might have recalled to her mind those feelings of passionate irritation with which she was affected in the beginning of the disease; whereas the feelings of maternal affection, being excited free from such associations, had time to acquire greater influence, till they became sufficiently powerful to fortify her against those passions by which they had been supplanted.

It appears from the view which Dr. Powell gives of the increase of returns made in different years since 1775, that insanity in Scotland in the number 259, the number of insane persons was 3489.

Of these, there were at large . . . . 2810

confined . . . . 649

Return of insane persons in Scotland, in number 982, with the exception of 259, the number of insane persons was 3489.

VOL XII. PART I.

Scotland.
INSANITY.

According to these returns, the proportions of the two sexes preponderate towards the females. This circumstance varies in different places. We are informed by Dr. Halliday, who at an early period made extensive inquiries on this subject, by collecting statements from the parishes of Scotland, that the proportion of natural idiots was greatest among males, while that of maniacal cases was greatest among females.

The parishes from which he obtained statements were 788. In these, the number of idiots going at large was 1076, of whom 1145 were males, and 831 females. That of maniacs under restraint was 1676, of whom 727 were males, and 949 females.

The objects of legislative enactment on the subject of insanity, comprise three particulars.

1. The prevention of wrongful confinement on a false plea of insanity. During a relaxed state of the law on this point, such confinement has very frequently been practised by selfish and depraved individuals, for the purpose of obtaining possession of the property of a rich relation. For this purpose false representations have been made to a medical practitioner, and the lure of emolument at the same time held out, and thus a certificate of insanity has been obtained, which was sufficient to authorize the confinement of any individual as a lunatic. Such a power ought not to be vested in any person whose qualifications are not well accredited; and the certificate of one individual should never be held sufficient to authorize the continuance of a person in confinement beyond a very few days. All such cases ought to be speedily reported to a plurality of official men. This is necessary for ascertaining, to the reasonable satisfaction of all parties, whether the insanity is evident; and cases will sometimes occur that bear a very questionable aspect, and require frequent visits, and the minute observation of a sagacious and experienced person, before that point can be determined. On this account facilities should be afforded for obtaining information from respectable neighbours, of all the previous circumstances that are likely to throw light on such cases. Wherever motives to unjust confinement might be supposed possible, the case should be investigated with particular care. Persons of property, being most liable to cruel imposition in this particular, should be provided with the best legal protection.

2. Another object is, to provide for the confinement of all those persons whose mental condition renders that measure necessary. On this point, delicacy towards persons who show symptoms of incipient derangement, and towards their friends, requires that much should be left to private discretion. There is no doubt, however, that wandering lunatics ought to be attended to; that the mischievous should be placed under restraint; and that, for obvious reasons, no females in this unfortunate situation should be allowed to go at large.

3. A third object is, to secure the best treatment to the insane who are placed in confinement. Even those who are really insane, especially persons of superior rank, are liable to be treated with studied carelessness from mercenary motives operating upon those into whose charge they are placed, and from the base antipathies or the rapacity of relations. Carelessness, mean resentment, and a brutal disposition to abridge, as much as possible, the business of a receptacle for the insane, have too often been productive of inhuman usage towards all descriptions of insane persons. These evils can only be prevented by an assiduous system of thorough and frequent inspection. Much advantage has arisen from some recent enactments providing for the inspection of such houses. But this inspection, in order to produce the desired effect, ought to be at least weekly, and the inspectors ought to have, without giving warning, immediate access to all parts of such establishments.

The arrangements required in lunatic hospitals have recently become a subject of attentive study, and it is hoped will soon be perfectly understood. The comfort of the situation, the security of the patients, and the prevention of mischief, are requisites in them all. More particular care is required in those intended for the reception of recent cases, which admit of some hopes of recovery. An hospital for the curable insane requires, besides the circumstances now mentioned, much more assiduous medical attendance, greater address on the part of the keeper, and various arrangements for separating the different classes of patients, for presenting to their feelings and thoughts only those objects which have an unexceptionable tendency, and providing them with salutary employment. Perhaps such institutions ought not to be committed exclusively to the care of one medical person. Or, if this is thought necessary for preventing jars, provision should be made for extended communications on the progress of each case, and frequent consultations on the minutiae of the treatment. Without this, the due interest in the object is apt to decline, and the practice is in danger of degenerating into an indolent routine.

INSECTA.

For the external anatomical structure, &c. see Zool.-

ORDER DIPTERA.

The characters of this order, and of the tribes of which it is composed, were given under the article ENTOMOLOGY, Vol. IX. p. 161.

SECT. I. PROBOSCIDEA.

Trib. I. TIPIARIDAE.

A. Antennae filiform or setaceous, longer than the head. Stirps 1. Ocelli none; antennae very hairy; eyes large; rostrum tubular, long.

Genus DCLXXXI. Culex, of authors.

Sp. 1. Pipiens of authors. The common gnat. Stirps 2. Ocelli none; antennae very hairy; eyes large; rostrum very short, terminated by two lips. Two anterior legs at a distance from the others.

Genus DCLXXXII. Corethra, Meig. Illig. Latr.

Antennae fourteen-jointed; the basal joints conico-ovoid; of the male with fasciules of hairs; with simple hairs on the females; the two last joints attenuated, elongated.

Tanytarsus. Meig.

Genus DCLXXXIII. Tanytarsus, Meig. Illig. Latr.

Antennae fourteen-jointed, very plumose, moniliform, their extremities filiform; of the male, almost entirely moniliform, their last joint larger and ovoid in the female.

Chironomus. Illig.

Antennae twelve-jointed, very plumose, moniliform, with filiform extremities in the male; seven jointed, the last joint elongate, cylindric in the female.

Inhabits Europe.

Stirps 3. Ocelli none, antennae very hairy, eyes large, rostrum very short, legs at an equal distance from each other.

Culicoides. Illig.

Genus DCLXXXV. Culicoides, Larr. Wings deflexed; rostrum conic, larger than the head; antennae fourteen-jointed, downy.

Inhabits France and England.

Psychoda. Illig.

Genus DCLXXXVI. Psychoda, Latr. Fabr. Ti-

nemaria, Scull. Trichoptera, Meig.

Wings deflexed, rostrum shorter than the head, ant-

tenna with fifteen or sixteen joints, of a globular form, covered with bundles of hairs.

Inhabits Europe.

Genus DCLXXXVII. Ceratopogon, Meig. Illig. Latr.

Wings incumbent; lower joints of the antennae ovate, or subglobular, the upper ones longer and cylindrical; the lower joints of the male with long bundles of hair.

Wings incumbent; antennae moniliform, hairy.

Stirps 4. Ocelli none; antennae with short hairs; eyes oval, entire; palpi with their last joint very long; lips not inclined.

Antennae filiform, pectinated in the males, serrated in the females; the second joint short, the third elongate.

Antennae subsetaceous, simple; the two first joints larger, elongate; the three following turbinate, the three next globular, and the seven last slender, cylindric.

Inhabits Europe.

Genus DCXCI. Tipula, of authors. Tipula.

Antennae subsetaceous, simple; the first joint largest, cylindric; the second subglobular; the next cylindric; the third elongate.

Inhabits Europe.

Genus DCXCII. Nephrotoma, Meig. Latr. Nephro-

toma.

Antennae subsetaceous, simple; the joints for the most part cylindric; those of the male arched.

Stirps 5. Ocelli none, antennae with short hairs; eyes oval, entire; palpi with their last joint very long; lips very long, inclined.

Genus DCXCIII. Ptychopteryx. Ptychopteryx, Pto-

Antennae subsetaceous, simple; the first joint sub-

obconic, third very long; the tenth, and three or four following joints subovate.

Stirps 6. Ocelli none, antennae with short hairs; eyes oval, entire; palpi with their last joint very long, and always simple.

Antennae moniliform, fourteen or sixteen jointed wings with three perfect discoidal cells.

INSECTA.

**Genus DCXCIV. Trichocera, Meig.**
Antennae setaceous, sixteen or fifteen jointed, the two first joints short, subequal, shorter than the third; wings with three perfect discoidal cells.

**Eriopteryx.**
*Genus DCXCIVI. Eriopteryx. Erioptera, Meig.*
Antennae subsetaceous, fifteen jointed, all the joints except the first quite moniliform; wings with two perfect discoidal cells.

**Hexatoma.**
*Genus DCXCVII. Hexatoma, Latreille.*
Antennae six jointed, subsetaceous, the two first joints shortest, the four others very long, cylindrical.
*Sp. 1. Nigrum.*
Hexatoma nigra. Latr.
Inhabits the vicinity of Paris.
*Stirps 7. Ocelli distinct; rostrum cylindrical, elongate.*

**Asindulum.**
Eyes within and behind notched; proboscis much longer than the head.

**Rhyphus.**
Eyes entire; proboscis porrect, a little shorter than the head.
*Sp. 1. Fenestraeum.* Latr.
Inhabits Europe.
*Stirps 8. Ocelli distinct; rostrum short, terminated by two lips.*

**Ceroplatus.**
*Genus DCC. Ceroplatus, of authors.*
Palpi very short; ovipositor conoid, obscurely uniarticulate; antennae compressed, fusiform.

**Molobrus.**
Palpi subglobiform, distinctly jointed; antennae subsetaceous; eyes sublunate; ocelli very distinct, placed near each other on the vertex.

**Myceotopilha.**
Palpi subglobiform, distinctly jointed; antennae subsetaceous; eyes entire, oval; ocelli very minute, distinct, the lateral ones placed one behind each eye.
B. Antennae massive or fusiform, and perforated.
*Stirps 9. Ocelli three; antennae nine-jointed.*

**Biblia.**
Thorax without spines on its anterior part; hinder tibiae produced into a strong hook.
Inhabits Europe.

**Dilophus.**
*Genus DCCIV. Dilophus, Meig. Illig. Latr.*
Thorax with its anterior and posterior margins pectinated; anterior tibiae with their apex and middle externally pectinate-dentate.
Inhabits Europe.

**Stirps 10. Ocelli three; antennae eleven-jointed.**

**Genus DCCV. Pentheteria, Meig. Latr.**
Eyes oval, entire.

**Genus DCCVI. Scathopsea, of authors. Ceria, Sco. Scathopsea.**
Eyes reniform or lunate.
*Stirps 11. Ocelli none.*

**Genus DCCVII. Cordyla, Meig. Latr.**
Antennae twelve-jointed; eyes entire.

**Genus DCCVIII. Simulium, Latr. Atractocera, Simulium, Meig.**
Antennae eleven-jointed; eyes lunate.

**Tribe II. Stratomydæ.**

A. Antennæ not terminated by a seta.
*Stirps 1. Antennæ with their last joint having eight rings.*

**Genus DCCIX. Hermetia, Latr. Fabr. Hermetia.**
Antennæ with their last joint much compressed, its middle strangulated.
*Sp. 1. Illucens.* Latr.

**Genus DCCX. Xylophagus, Meig. Fabr. Latr. Xylophagus.**
Antennæ cylindrical, the last joint cylindrical-conic, elongate; scutellum without spines; palpi longer than the proboscis.

**Genus DCCXI. Actina, Meig. Actina.**
Antennæ cylindrical, the last joint cylindrical-conic, elongate; scutellum with six spines; palpi not longer than the proboscis.

**Genus DCCXII. Beris, Latr. Beris.**
Antennæ cylindrical, the last joint cylindrical-conic, elongate; scutellum with four or six spines; palpi very much shorter than the proboscis.
*Stirps 2. Antennæ, with their last joint having from four to six rings, fusiform, cylindrical-conic, or conic.*

**Genus DCCXIII. Stratomyia, of authors. Stratomyia.**
Antennæ very much longer than the head, the first and third joints very long, the latter subglobiform, compressed, with five rings; thorax bispinous.
Inhabits Europe.

**Genus DCCXIV. Odontomyia, Meig. Illig. Latr. Odonto-**
Antennæ a little longer than the head, the last joint myia, cylindrical-conic, with six rings; thorax bispinous.
Inhabits Europe.

**Genus DCCXV. Citellaria, Meig. Illig. Ephipp. Citellaria.**
*Pium, Latr.*
Antennæ a little longer than the head, with their last joint conic, six-ringed, the two last forming a little style; thorax bispinous, the spines erect.
INSECTA.

Inhabits Europe.

Genus DCCXVI. NEMOTELUS, of authors.
Antennae half the length of the head, the third joint fusiform, four-ringed; scutellum without spines; proboscis sheathed beneath a rostelliform process, on which the antenna are inserted.
Inhabits Europe.

b. Antennae terminated by a style or seta.

Genus DCCXVII. OXYCEVA, Meig. Illig. Latr.
Antennae with their first and second joints forming a subfusciform club, the third styliform.
Inhabits Europe.

Stirps 4. Scutellum without spines.

Genus DCCXVIII. VAPPOR Latr. Fabr. PACHYGASTER, Meig.
Antennae, with their two first joints transverse, the second with the third joints forming a sub-hemispheric head.
Inhabits Germany and England.

Genus DCCXIX. SARUS, of authors.
Antennae terminated by a seta longer than the antenna, their second joint elongate; abdomen generally oblong.
Sp. 1. Xanthopterus Fabr.

Tribe III. TABANIDES.
Stirps 1. Wings incipient; scutellum spinous.

Genus DCCXX. OXONOMYIA, Latr.
Antennae shorter, or scarcely longer than the head; the second joint subbovine, short; the third longer, elongate-conic, distinctly eight-ringed; ocelli three.
Stirps 2. Wings divaricating; scutellum without spines; antennae as long as, or a little longer, than the head.

Genus DCCXXI. PANGONIA, Latr. Fabr. TANYGLOSIS, Meigen.
Proboscis siphunculiform, coriaceous, very long, subporrect or subnutant; antenna scarcely as long as the head; the second joint sub-transverse; the third longer, elongate-conic, sub-arcuate, distinctly eight-ringed; ocelli three.

Genus DCCXXII. TABANUS, of authors.
Proboscis a little shorter than the head, terminated by large lips; antenna as long as the head, the second joint cup-shaped, the third lunate-subulate, five-ringed; ocelli obsolete or wanting.
Stirps 3. Wings divaricating; scutellum without spines; antennae remarkably longer than the head.

Antennae with their first joint elongate, incassate; the second very short, cup-shaped; the third elongate-conic, (longer than the first) tubulated, four-ringed: ocelli obsolete or wanting.
Inhabits Europe.

Antennae formed of cylindric joints; the second shortest; the third very long, four-ringed: ocelli obsolete or wanting.

Antennae, with the two first joints of nearly an equal length, the third joint as long as both the others, cylindric-conic, five-ringed; ocelli three.
Inhabits Europe.

Tribe IV. RHAGIONIDES.

Genus DCCXXVI. PACHYSTOMUS, Latr. Pachysto-
mus.
Antennae cylindric; third joint three-ringed, without a seta.
Inhabits Germany.

Leptis, Fabr.
Antennae moniliform, the third joint not ringed, but terminated by a seta; palpi rect.
Inhabits Europe.

Genus DCCXXVIII. ATERIX, Meig. Latr. Atherix.
Antennae moniliform, the third joint not ringed, but terminated by a seta; palpi erect.
Inhabits Europe.

Genus DCCXXIX. ORTOCHILIS, Latr. Ortochile.
Antennae terminated by a globose head, bearing a terminal seta.
Inhabit the vicinity of Paris.

Tribe V. DOLYCHOPIDES.

Genus DCCXXX. PLATYPESA, Meig. Platypesa.
Antennae as long as the head, their last joint very long, terminated by a seta; hinder tarsi compressed, the third joint largest.
Inhabits Europe.

Genus DCCXXXI. CALLOMYIA, Meig. Callomyia.
Antennae as long as the head, their last joint very long, terminated by a seta; hinder tarsi filiform, the first joint largest.

Genus DCCXXXII. DOLYCHOPUS, Latr. Fabr. Walc. Dolycho-
Antennae half the length of the head, the third joint pim, trigonal, bearing a seta on its hinder part.

* This genus probably ought to be placed in the second Stirps.
Tribe VI. Mydasides.

Genus DCCXXXIII. Mydas, Fabr. Latr.
Antennae longer than the head; the last joint very long, its point ovate-clavate, truncate, concave; the concavity including an obscure little style. Sp. 1. Filata. Fabr.
Inhabits North America.

Tribe VII. Asilides.

Stirps 1. Tarsi terminated by two claws, and two pulvilli; antennae as long, or not much longer than the head.

Inhabits Europe.

Tribe VIII. Empides.

Stirps 1. Proboscis perpendicular.

Tribe IX. Anthracides.

Tribe X. Bombylides.

Stirps 1. Proboscis never longer than the head, its point incrassated; antennae with their first joint longest, and thicker than the third.

Genus DCCL. Tachydromia, Meig. Fabr.
Genus DCCL. Usa, Latr.

Palpi not distinct; antennae with their two first joints short and equal.

**TRIBE XI. ACROCRIDES.**

\textit{Stirps} 1. Proboscis distinct; antennae two or three-jointed, with or without a terminal seta.

Genus DCCLI. Panops, Lam. Latr.

Antennae longer than the head; three-jointed, the last joint elongate, cylindrical, without a terminal seta.

Sp. 2. Proboscis obscure; antennae three-jointed, not terminated by a seta.

Genus DCCLII. Cirrus, Latr.

Antennae very small, two-jointed; the last joint ovoid, with a terminal seta.

Genus DCCLIII. Astomella, Dufour, Latr.

Inhabits Spain.

Genus DCCLIV. Acroceras, Meig. Latr.

Antennae inserted on the vertex.

Antennae inserted anteriorly over the cavity of the mouth.

Inhabits Germany and England.

**TRIBE XII. SYRPHIDAE.**

Genus DCCLVI. Rhinogia, of authors.

Head anteriorly much produced, terminated by the proboscis.

Sp. 1. \textit{Rourata}, of authors.

Inhabits Europe.

Genus DCCLVII. Sericomia, Latr.

Antennae with their seta plumose, inserted at the dorsal juncture of the second and third joints; last joint of the antennae subarticulate.

Inhabits Europe.

Antennae with their last joint elongate; seta plumose, inserted at the dorsal juncture of the second and third joint.

Inhabits Europe.

**GENUS DCCLI. IX. Evisialis, Latr. Fabr. Heliophilus, Meig. Illig.**

Antennae contiguous at their base, their last joint broader than long; seta (simple or slightly plumose) inserted beyond the dorsal junction of the second and third joints; head anteriorly distinctly rostriform.

Antennae contiguous at their base; their third joint longer than broad; seta (simple or slightly plumed) inserted beyond the dorsal juncture of the second and third joints; head anteriorly distinctly rostriform.

Inhabits Europe.

Genus DCCLXI. Syrphus, of authors.

Syrphus.

Antennae separate at their base; their last joint sub-orbicate; seta inserted beyond the dorsal juncture of the second and third joints; abdomen elongate-subquadrate, gradually somewhat narrower towards its extremity.

Inhabits Europe.

Genus DCCLXII. Doros, Meig. Illig.

Doros.

Antennae separate at their base; their last joint sub-orbicate; seta inserted beyond the dorsal juncture of the second and third joints; abdomen clavate, contracted at each side of its base.

Sp. 1. \textit{Comopses.}

Meilesia comopesa. Fabr.

Syrphus coarctatus. Panz.

Inhabits Europe.

Genus DCCLXIII. Scena, Fabr.

Scena.

Antennae separate at their base; their last joint sub-ovate; seta inserted beyond the dorsal juncture of their second and third joints; abdomen subovate trigonal; the length double the breadth.

Inhabits Europe.

Sp. 2. Head not anteriorly conic-produced; antennae about the length of the head, placed in a common elevation; oval cavity on the nasal prominence; wings deflexed or slightly disarticulating.

Genus DCCLXIV. Paragus, Latr.

Paragus.

Antennae separate at their base; their two first joints subequal; seta simple, not distinctly articulated.

Genus DCCLXV. Psarus, Latr. Fabr.

Psarus.

Antennae inserted on a common elevation; the second joint larger than the first; seta thick, styliform, distinctly biarticulate.

Sp. 1. \textit{Abdominalis}. Fabr.

Sp. 2. Head not anteriorly conic-produced; antennae very much longer than the head; placed on a common elevation; oval cavity on the nasal prominence; wings deflexed.

Antennae subarticulate; their last joint having a seta um.

Inhabits Europe.

**Genus DCCLXVII. Ceria, Fabr. Latr. Illig. Meig.**
Antennae with their first and second joints forming an oval mass terminated by a style.
Inhabits Italy and Barbary.

**Calligera.**

**Genus DCCLXVIII. Calligera, Meig. Panz.**
Antennae with their first and second joints forming an elongate mass, terminated by a style.
Inhabits Europe.

**Spirs. 4.** Head not anteriorly produced; nasal part straight, not prominent; antennae inserted separately, very much longer than the head; wings deflexed.

**Apenopus.**

**Genus DCCLXIX. Apenopus, Latr. Micronota, Meig.**
Antennae with their third joint conic, elongate, its base bearing a seta.
Inhabits Europe.

**Stirps. 5.** Head not anteriorly produced, nasal parts concave or straight; antennae inserted separately, very much shorter than the head.

**Micronota.**

**Genus DCCLXX. Micronota, Meig. Fabr. Latr.**
Hind legs (of the male at least) large, very thick, arcuate, points produced into a strong tooth; antennae with their joints trigonal.
Inhabits Europe.

**Eumenos.**

**Genus DCCLXXI. Eumenos, Meig.**
Hind legs (of the males at least) large, very thick, elongate ovate, denticulated beneath; antennae with their last joint much compressed; abdomen cylindric.
Inhabits Europe.

**Milesia.**

**Genus DCCLXXII. Milesia, Latr. Leach.**
Hind legs (of the males at least) large, very thick, elongate ovate, denticulated beneath; antennae with their last joint much compressed; abdomen trigonal.
Inhabits Europe.

**Spilomyia.**

**Genus DCCLXXIII. Spilomyia, Meig. Heliophillus, Meig.**
Hind legs (of the males at least) large, thick, elongate, subcylindric; antennae with their last joint short, subovate, much compressed.
Inhabits Europe.

**Chrysogaster.**

**Genus DCCLXXIV. Chrysogaster, Meig.**
Hind legs not different from the others; antennae with their last joint elongate-conic, much compressed.
Inhabits Europe.

**Tribe XIII. Conopside.**

**Stirps. 1.** Antennae with their second joint as long, or longer than the third, forming with it a fusiform, or subovate compressed club; body elongate.

**Genus DCCLXXV. Conopside. of authors. Conopside.**
Proboscis procer; ocelli none; antennae very much longer than the head, apex fusiform.
Inhabits Europe.

**Genus DCCLXXVI. Zodion, Latr. Zodion.**
Proboscis procer; ocelli three; antennae shorter than the head, apex subovoid.
Inhabits Italy and France.

**Genus DCCLXXVII. Myopa, of authors. Stomox. Myopa.**
Proboscis very long, filiform geniculated beneath twice.
Inhabits Europe.

**Stirps. 2.** Antennae with their second joint much smaller than the last, which is patelliform; body short.

**Genus DCCLXXVIII. Bucentes, Latr. Bucentes.**
Proboscis geniculated twice.
Inhabits France and England.

**Genus DCCLXXIX. Stomoxys, of authors. Stomoxys.**
Proboscis geniculated once.
*Sp. 1. Calicistrans, of authors.*
Inhabits Europe.

**Tribe XIV. Muscide.**

**Stirps. 1.** Antennae inserted near the mouth; palpi external.

**Genus DCCLXXX. Phora, Latr. Trineura, Meig. Phora. Phora.**
Antennae with the two first joints very minute, obsolete, the third thick, subglobose, furnished with a long seta.
Inhabits Europe.

**Stirps. 2.** Antennae inserted near the front, setigerous; palpi internal; halteres visible; anterior legs simple; head subglobose; hinder legs very large.

**Genus DCCLXXX. Spilarocera, Latr. Borbo- Spilarocera.**
Hind legs? Meig.
Antennae almost completely exserted, last joint semi-orbicular.
Inhabits Europe.

**Genus DCCLXXXII. Thyreophora, Meig. Illig. Thyreophora.**
Antennae almost entirely concealed within a deep excavation in the front, last joint globular.
Inhabits Europe.

**Stirps. 3.** Antennae inserted near the front, setigerous; palpi internal; halteres visible; anterior legs simple; head not subglobose; hinder legs not larger than the rest; wings horizontal; eyes sessile.
INSECTA.

Inhabits Europe.

Mulio, Schellenberg.

Antennae very much longer than the head; inserted on an elevation; the second joint very long, cylindrical.

Inhabits Europe.

Antennae very much longer than the head; last joint linear; abdomen narrow, linear.

Inhabits Europe.

PA, Illig.

Antennae shorter than the head; head round, subglobose; vertex horizontal; body very much elongated.

Inhabits Europe.

Antennae shorter than the head; head hemispheric, transverse; vertex inclined; body not much lengthened.

Inhabits Europe.

Stirps 7. Antennae inserted near the upper part of the head, not setigerous; palpi internal; halteres visible; anterior legs differing in form from the others.

Genus DCCXVII. Pipunculus, Latr. Pipunculus.

Antennae two-jointed; anterior legs simple.

Inhabits Europe.

Schellenberg.

Antennae three-jointed; anterior legs simple.

Inhabits Europe.

Genus DCCXIX. Obturia, Latr. Macrochira, Obturia.

Meig.

Anterior legs raptorial; antennae terminated by a bearded seta.

Inhabits Europe?

Stirps 8. Antennae frontal; palpi internal; halteres entirely or partly concealed; wings deflexed.

Genus DCC. Lipse, Latr.

Lipse.

Legs all alike.

Stirps 9. Antennae frontal, very short; palpi internal; halteres entirely or partly concealed; wings divaricating.

Genus DCCXI. Melanophora. Latr. Melanophora.

Antennae contiguous at their base, diverging, last joint lenticular.

Genus DCCXII. Metopia, Latr. Metopia.

Antennae contiguous at their base, diverging, last joint oblong.

Inhabits Europe.

Genus DCCXIII. Phasia, Latr. Leach. Thereva, Phasia.

x
Insecta.

Antennae distant, sub-parallel, last joint subcubadate, with a biarticulate seta; (body short; abdomen depressed, semicircular; wings large.)

Genus DCCCV. Musca, of authors.
Antennae with the third joint very much longer than the others; abdomen moderately long, subcubate.

Genus DCCCV. Ocypteryx, Leach. Oxyptera, Latr.

Common blue-bottle fly. Inhabits Europe.

Genus DCCCV. Ocypteryx, Leach. Oxyptera, Latr.

Exonista, Meig. Eriothrix, Meig.
Antennae with their last joint longer than the others; abdomen distinctly annulated, rouqided.

Inhabits Europe.

Genus DCCCVI. Gymnosoma, Meig. Leach.

Antennae with their last joint longer than the others; abdomen semicircular, subcubate.

Inhabits Europe.

Antennae with their second joint longer than the others; abdomen subglobose, and very bristly.

Inhabits the European woods.

Genus DCCCVIII. Tachina.

Antennae with their second joint longer than the others; abdomen ovate, rather bristly.

Sp. 1. Fera.
Musca fera. Linné.
Inhabits the European woods.

Tribe XV. Oestrizes.

The larvae of all the insects composing the present family reside in the frontal sinuses, under the skin, or in the stomachs, of graminivorous mammalia. Their curious economy has been admirably detailed in the third volume of the Transactions of the Linnean Society of London, by Dr. Bruce Clark, who has lately republished his Dissertation, under the title An Essay on the Bots of Horses and other animals. London, 1815.

Genus DCCCV. Oestrus, of authors.

Wings, with the two exterior hinder cells complete, the other hinder cells terminal. Thorax with its surface unequal. Abdomen with its point deflexed; of the female scutuminate. Eyes distant; of the male closer than those of the female.

* Thorax roughish, with elevated points.

The larvae of the species of this division of the genus inhabit the frontal sinuses.

Inhabits the frontal sinuses of the sheep in the larval state; the perfect insect is found on walls and stones in the vicinity of sheep-folds.

** Thorax with square shining naked spots.

The larvae of this section reside beneath the skin of herbivorous mammalia.

Sp. 2. Bovis.
The larvae of this species, named by the peasants Warbles or Worms, "are found beneath the skin on the backs and loins of oxen, causing tumours as large as pullets eggs." The perfect insect, a gallfly, is found about the end of summer, and is much dreaded by oxen.

Genus DCCCV. Gasterophilus, Leach. Oestrus, Gasterophilus, of authors.

Wings, with all the hinder cells terminal. Thorax, with its surface smooth. Abdomen, with its extremity infixed; of the female, very much elongated and attenuated. Eyes, in both sexes, equally distant.

The larvae of the Gasterophilus, as their name imports, inhabit the stomach of herbivorous quadrupeds, and are called bots; the perfect insects Botflies.

Oestrus Bovis. Linné.
The larva inhabits the horse.

Sect. II. Euphobaidea.

The larvae are nourished within the abdomen of the mother, and when full grown, are passed in the form of an oviform pupa, covered with the infusated skin of the larva. We have described the species in the second volume of the Memoirs of the Wernerian Natural History Society of Edinburgh.

Stirps 1. Wings, two; the hinder cell only commenced. Thorax anteriorly entire, acuminated.

Genus DCCCVI. Hippobosca, of authors. Hippobosca.
Ocelli, none.
Inhabits the horse, and is vulgarly called Forester.
Stirps 2. Wings, two; the hinder cells complete. Thorax anteriorly notched for the reception of the head.

* Wings of nearly an equal breadth throughout.

Ocelli, none.

Ornithomyia.
Ocelli, three, situated in the eye.
Hippobosca Avicularia. Linné.
Inhabits the black grous and tit pipit.

** Wings acuminated.

Genus DCCCV. Sterepteryx, Leach. Sterepteryx.
Ocelli, three.
Inhabits the nests and bodies of the house-swallow.

Genus DCCCV. Oxypteryx. Kirby, MSS. Leach. Oxypteryx.
Ocelli, none.
Inhabits England.
Stirps 3. Wings, none. Thorax anteriorly notched for the reception of the head.

Ocelli, none.
Inhabits the sheep.

### INSECTS.  SEE BEE, CRUSTACEOLOGY, ENTOMOLOGY, PHYSIOLOGY, AND ZOOLOGY.

**INSTINCT.** See Moral Philosophy.

INSTITUTE, National of France, or, as it is now called, the Institute of France, was established on the suggestion of Condorcet, in the year 1795, and was opened on the 7th of December of that year, by Benezet, the Minister for the Home Department. It was formed out of the Royal Academy of Sciences, the French Academy, the Academy of Inscriptions and Belles Lettres, and the Academy of Painting and Sculpture, &c. It was re-organized in 1806, during the consulate of Bonaparte, and it again experienced considerable changes in the year 1816, after the return of the Bourbons.

In order to understand the changes which this distinguished body has recently undergone, we shall first lay before our readers an account of the National Institute as it existed in the time of Bonaparte.

The National Institute consisted of four classes, viz.

1. Class of physical and mathematical sciences.
2. Class of French language and literature.
3. Class of history and foreign literature.
4. Class of the fine arts.

**First class.**

The first class shall be formed of the ten sections which at present compose the first class of the institute, with a new section of geography and navigation, and eight foreign associates.

The sections shall be composed and named as follows:

<table>
<thead>
<tr>
<th>Mathematical Sciences.</th>
<th>Corresponding Members</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geometry</td>
<td>6</td>
</tr>
<tr>
<td>Mechanics</td>
<td>6</td>
</tr>
<tr>
<td>Astronomy</td>
<td>6</td>
</tr>
<tr>
<td>Geography and Navigation</td>
<td>3</td>
</tr>
<tr>
<td>General Physics</td>
<td>6</td>
</tr>
<tr>
<td>Chemistry</td>
<td>6</td>
</tr>
<tr>
<td>Mineralogy</td>
<td>6</td>
</tr>
<tr>
<td>Botany</td>
<td>6</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Physical Sciences.</th>
<th>Corresponding Members</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rural Economy and the Veterinary Art</td>
<td>6</td>
</tr>
<tr>
<td>Anatomy and Zoology</td>
<td>6</td>
</tr>
<tr>
<td>Medicine and Surgery</td>
<td>6</td>
</tr>
</tbody>
</table>

The first class shall appoint, with the approbation of the First Consul, two perpetual secretaries, one for the mathematical sciences, the other for the physical sciences. The perpetual secretaries shall be members of the class, but shall not form a part of any section.

The first class may elect six of its members from the other classes of the institute.

It may name an hundred correspondents selected from the learned men of France and foreign countries. III. The 2d class shall be composed of 40 members.

It is particularly charged with the composition of the dictionary of the French language. It shall examine, with respect to language, the important works of literature, history, and the sciences. The collection of its critical observations shall be published at least, four times in a year.

It shall name from its own body, and with the approbation of the First Consul, a perpetual secretary, who shall continue to be of the number of the forty members which compose it.

It may elect twelve of its members from the other classes of the institute.

IV. The third class shall be composed of forty members and eight foreign associates.

The object of its researches and labours shall be learned languages; antiquities and monuments; history, and all the moral and political sciences connected with history. It shall particularly apply itself to the enriching of French literature with the works of Greek, Latin, and Oriental authors, which have not yet been translated.

It shall employ itself in the continuation of diplomatic collections.

It shall name from its own body, under the approbation of the First Consul, a perpetual secretary, who shall be of the number of the forty members which compose the class.

It may elect nine of its members from the other classes of the institute.

V. The fourth class shall be composed of twenty-eight members and eight foreign associates.

They shall be divided into sections, as follows:

- Painting | 10 members.
- Sculpture | 6 ditto.
- Architecture | 6 ditto.
- Engraving | 3 ditto.
- Musical composition | 3 ditto.

It shall appoint, with the approbation of the First Consul, a perpetual secretary, who shall be a member of the class, but shall not be a part of a section.

It may elect six of its members from the other classes of the institute.

The first class shall appoint, with the approbation of the First Consul, two perpetual secretaries, one for the mathematical sciences, the other for the physical sciences. The perpetual secretaries shall be members of the class, but shall not form a part of any section.
It may name 36 correspondents national or foreign.
VI. The foreign associated members shall have a deliberative voice only on subjects of science, literature, and the arts; they shall not form part of any section, nor interfere in any usage.

VII. The present actual national associates of the institute shall form part of the one hundred and ninety-six correspondents attached to the classes of the sciences, belles lettres, and fine arts.

Correspondents may not assume the title of members of the institute.

They shall lose that of correspondent when they shall be domiciled at Paris.

VIII. Nominations to vacant places shall be made by each class in which the vacancy happens; the persons elected shall be confirmed by the First Consul.

IX. The members of the four classes shall enjoy a reciprocal right to assist at the particular sittings of each class, and may deliver lectures when they are requested.

They shall re-unite four times in a year into one body, to communicate their proceedings.

They shall elect in common the librarian and under librarian of the institute, as well as all those agents who belong to the institute in common.

Each class shall present for the approbation of the government, the particular statutes and regulations of its internal police.

X. Each class shall hold one public sitting every year, at which the other three shall assist.

XI. The institute shall receive annually from the public treasury 1500 fr. for each of its non-associated members, 6000 fr. for each of its perpetual secretaries; and for its expenses, a sum which shall be fixed every year, upon the demand of the institute, and comprised in the estimates of the minister of the interior.

XII. There shall be an administrative committee of the institute, composed of five members, two from the first class, and one from each of the others, named by their respective classes.

This committee shall regulate in the general sittings prescribed by art. X. all that relates to the administration, to the general expenses of the institute, and to the division of its funds between the four classes.

Each class shall afterwards regulate the application of the funds assigned to it for its expenses, as well as all that concerns the printing and publishing its memoirs.

XIII. The classes shall annually distribute prizes, thus regulated:

The first class, a prize of 3000 francs.

The 2d and 3d class, each a prize of 1500 francs.

The fourth class, grand prizes of painting, sculpture, architecture, and musical composition. Those who gain one of the grand prizes shall be sent to Rome, and maintained at the expense of government.

On the 21st March, 1816, an order was issued by Louis XVIII. for new-modelling the Institute, of which the following is an abstract:

1. The Institute shall be composed of four academies, viz.

The French Academy.

The Royal Academy of Inscriptions and Belles Lettres.

The Royal Academy of Sciences.

The Royal Academy of the Fine Arts.

2. The academies are under the direct and special protection of the king.

3. Every academy shall have an independent regime, and the free disposal of the funds which belong to it.

4. The agency, the secretariat, the library, and the other collections of the Institute, shall remain common to the four academies.

5. The property common to the four academies, and the common funds which belong to them, shall be managed under the authority of the Secretary of State for the Interior, by a commission of eight members, of which two shall be taken from each academy. These commissioners shall be elected annually, and shall be always re-eligible.

6. The property and funds of each academy shall be managed in its name by the boards or commissions, instituted for this purpose.

7. The academies shall hold a common public sitting on the 24th April, the day on which the Bourbons returned to France.

8. The members of each academy may be elected to the three other academies.

9. The French Academy shall reserve its ancient French statutes, with such modifications as may be thought necessary.

10. It shall be composed of thirty-eight members.

11. The Academy of Inscriptions and Belles Lettres Royal shall preserve the organization of the actual rules of the third class of the Institute.

12. It shall be composed of thirty-seven members.

13. The Royal Academy of Sciences shall preserve Royal society, and the distribution into sections of the deny of the first class of the Institute.

14. The Royal Academy of the Fine Arts shall preserve the organization and the distribution into sections of the deny of the fourth class of the Institute.

15. It shall be composed as follows:

Painting
Sculpture
Architecture
Engraving
Musical composition

14 members.
8 members.
5 members.
4 members.
6 members.

16. There shall be added to the Royal Academy of General regulations.

Inscriptions and Belles Lettres, and to the Royal Academy of Sciences, a class of free academicians to the number of 10 to each of these two academies.

17. The free academicians shall have no other privilege than that of the right of attendance. They shall enjoy the same rights as the other academicians, and shall be elected according to the usual forms.

18. The ancient honorary members and academicians of both the Royal Academy of Sciences and of the Royal Academy of Inscriptions and Belles Lettres, shall be free academicians of the academy to which they belong.

These academicians shall make the necessary elections for completing the number of ten free academicians in each.

19. The Royal Academy of Fine Arts shall likewise have a class of free academicians, of which the number shall be determined by a particular regulation upon the proposition of the academy itself.

20. The Minister of the Interior shall submit to the king for his approbation the modifications which may be thought necessary in the regulations of the first, third, and fourth classes of the Institute, for adapting the said regulations to the Royal Academy of Sciences, to the Royal Academy of Inscriptions and Belles Lettres, and to the Royal Academy of the Fine Arts.

21. All the decrees and regulations which contain nothing contrary to the regulations of the present ordonnance shall be maintained.

The following is a correct statement of the volumes of memoirs published by the Institute of France:
Institution.

Number of volumes published from the foundation of the Institute till 1806, by the three classes............ 16 in 4to.
Number of volumes published from 1806 to 1812.
Volumes published by the Academy of Sciences............ 7
Academy of Inscriptions............ 4
Memories de Savans Etrangers............ 2
Systeme Metrique............ 3
Etat du Science et des Lettres............ 2
Prix Decennaux............ 1

Total............ 35 vols.
The volumes of memoirs for 1813, 1814, 1815, and 1816, have not yet appeared.

INSTITUTION, AFRICAN, a society for promoting the civilization of Africa, established in London in the spring of 1807. It may be considered as a continuation of the Abolition Society; and owes its origin to a few of the most indefatigable opponents of the slave trade, who were nobly bent upon following up every practicable measure for the utter extirpation of that execrable traffic, and for compensating, by every benefit in their power, the injuries which it had so long entailed on the African continent. It was readily and cordially befriended by the first, by the leading members of that administration, who had accomplished the measure of abolition in parliament; and who, though dispossessed at the time of all official power, were consistently persevering in the prosecution of a cause, which ought ever to have reigned paramount over all party views and feelings. These, however, proved too powerful for a time, for the halls of common humanity and of Christian principle; and the keen political contests which then agitated the kingdom, prevented that concurrence of the abolitionists, which might have been expected in the objects of the institution. Hence it was almost entirely neglected, till the return of more peaceful times; and till the appearance of the first report of its committee in midsummer of 1807, brought its claims more effectually before the public. To that report, generally understood to have been drawn up by Mr. Stephen, we must refer for an able statement of the objects of the institution, and the means proposed to be pursued for their attainment, and content ourselves with extracting the resolutions adopted at the same meeting, as containing the best summary of its general views.

1. That this meeting is deeply impressed with a sense of the enormous wrongs which the natives of Africa have suffered in their intercourse with Europe; and, from a desire to repair those wrongs, as well as from general feelings of benevolence, is anxious to adopt such measures as are best calculated to promote their civilization and happiness.

2. That the approaching cessation of the slave trade, hitherto carried on by Great Britain, America, and Denmark, will, in a considerable degree, remove the barrier which has so long obstructed the natural course of social improvement in Africa; and that the way will be thereby opened for introducing the comforts and arts of a more civilized state of society.

3. That the happiest effects may be reasonably anticipated from diffusing useful knowledge, and exciting industry among the inhabitants of Africa, and from obtaining and circulating throughout this country more ample and authentic information concerning the agricultural and commercial fac.ulties of that vast continent; and that, through the judicious prosecution of these benevolent endeavors, we may ultimately look forward to the establishment, in the room of that traffic, by which Africa has been so long degraded, of a legitimate and far more extended commerce, beneficial alike to the natives of Africa, and to the manufacturers of Great Britain and Ireland.

4. That the present period is eminently fitted for prosecuting these benevolent designs; since the suspension during the war of that large share of the slave trade, which has commonly been carried on by France, Spain, and Holland, will, when combined with the effect of the abolition laws of Great Britain, America, and Denmark, produce nearly the entire cessation of that traffic along a line of coast extending between two and three thousand miles in length, and thereby afford a peculiarly favorable opportunity for giving a new direction to the industry and commerce of Africa.

5. That, for these purposes, a Society be immediately formed, to be called "The African Institution."

6. The society, disclaiming all projects of a colonial or commercial nature, and likewise all schemes of religious instruction, (though neither indifferent nor hostile, but rather subservient and friendly, to that important object,) proposed to adopt the following means for promoting the civilization and improvement of Africa.

1. To collect and diffuse throughout this country accurate information respecting the natural productions of Africa, and in general respecting the agricultural and commercial capacities of the African continent, and the intellectual, moral, and political condition of its inhabitants.

2. To promote the instruction of the Africans in letters and in useful knowledge, and to cultivate a friendly connection with the natives of that continent.

3. To endeavour to enlighten the minds of the Africans with respect to their true interests, and to diffuse information amongst them respecting the means, whereby they may improve the present opportunity of substituting a beneficial commerce in place of the slave trade.

4. To introduce amongst them such of the improvements and useful arts of Europe, as are suited to their condition.

5. To promote the cultivation of the African soil, not only by exciting and directing the industry of the natives, but by furnishing, where it may appear advantageous to do so, useful seeds, and plants, and implements of husbandry.

6. To introduce amongst the inhabitants beneficial medical discoveries.

7. To obtain a knowledge of the principal languages of Africa, and, as has already been found to be practicable, to reduce them to writing, with a view to facilitate the diffusion of information among the natives of that country.

8. To employ suitable agents, and to establish correspondences, as shall appear advisable; and to encourage and reward individual enterprise and exertion in promoting any of the purposes of the institution.

As a general, rather than particular mean of promoting the whole views of the institution, its members devote their individual attention, and united influence, to the enforcement of the abolition laws, and the exposure of every attempt to evade their efficacy.

Among the foremost of this society's patrons may be mentioned the Duke of Gloucester, who presided as president at its first establishment; and its original committee, which consisted of the following persons, namely, Earl Spencer, Moira, and Euston; Viscounts Howick and Valentia; the Bishops of London, Durham, Bath, Wells, and St. David's; Lords Grenville, Ellenborough, Erskine, Holland, Teignmouth, Headley, and Henry Petty; the Chancellor of the Exche-
quer (Mr. Perceval), the Right Hon. T. Grenville, G. Canning, J. C. Villiers, Sir J. Newport, J. F. Foster, J. Smith, and N. Van Sittart, Sir P. Francis, Sir S. Romilly, General Vyne, Messrs. Banke, Babington, Bar- ring, J. H. Browne, Baray, Grant, Huskisson, Lushington, Montague, W. M. Pitt, Roscoe, Sharp, Simeon, R. Thornton, H. Thornton, Whitbread, and Wilber- force, (members of parliament); and Messrs. Bernard, Bercley, Brougham, Clarkson, Gisborne (Rev.) Martin, Maccallim, G. Sharp, W. Smith, Stephen, and Venn (Rev.) Mr. Macaulay undertook, in the interest, and for several years most ably discharged, the labo- rious office of secretary, in which he has been succeed- ed by T. Harrison, Esq. The income of the society amounted at the end of 1808 to £2,457, which of £253 arose from annual contributions; and though its funds have subsequently been much augmented by subscrip- tions and donations, (one of which, to the amount of 500 guineas, was transmitted anonymously from a member of the Society of Friends,) they have by no means been proportionate to the extent and interest of its objects.

Of its well directed and generally successful pro- ceedings, a very slight sketch only can here be pre- sented; but its reports may be recommended to our readers, as most interesting to the friend of humanity, by the importance of their topics, the attractiveness of their form, the elegance of taste, by the ability and eloquence with which they are executed—and even amusing to the idler, by the variety and curious nature of their contents. In the course of the first two years of its existence, the institution sent out to Sierra Leone three African youths, instructed by Dr. Bell and Mr. Lancaster; and directed the governor of the settlement, to select other young men to be sent to England, for the purpose of being qualified to act as teachers in such branches of knowl- edge as might be most beneficial in Africa, particu- larly to engage proper persons to teach in that country the Arabic and Sassoio languages: conveyed to various parts of the coast, large quantities of the best kinds of cotton seed, to be distributed among the natives for cul- tivation, and also a number of machines for cleaning the cotton; which printed directions to its whole culture and management: sent a press, on a new construction, for expressing the oil of the castor nut, with a number of plants of the white mulberry tree, to ascertain the possibility of raising silk in Africa; besides the seeds and plants of other valuable productions, such as the genuine Peruvian bark, camphor, tea-tree, and tobacco: offered premiums for the importation of cotton, wool, rice, and indigo from Africa, and for the growth of coffee in that country; while, at the same time, they exerted their influence with government to procure a modification of the heavy duties on articles from the African coast: counteracted, with considerable effect, the numerous nefarious attempts to infringe the abolition laws, and both by public representations, and the cultivation of suitable tracts in French, Dutch, Portu- guese, and Spanish, have endeavoured to induce for- eign powers to abandon the traffic in slaves. Upon finding that the culture of the mulberry tree had pro- 

fore parliament, which was passed unanimously in both houses, for declaring the slave trade a felonious crime; in preparing the way for establishing in the West Indies a registry of slaves, for the purpose of checking all illicit importation of new negroes, as well as for securing the better treatment of those already in bondage; and in standing forward as the advocates of op- pressed Africans, both at home and abroad. "After the universal expression of the public feelin, which we have witnessed," says one of these able advocates, (referring to the petitions presented to parliament in 1814, on the negotiations for procuring the abolition of the slave trade by foreign powers,) "it is with surprise and concern we perceive, how very inade- quate to the variety and immensity of its objects the funds of this admirable institution still are. Its recent invaluable efforts have nearly exhausted them; and its permanent income falls at present (1815) considerably short of £500 per annum. This circumstance would undoubtedly be somewhat opprobrious to the British name, and especially to the religious part of the com- munity, if it did not proceed, as we feel confident it does, from ignorance of the real state of the case. It cannot be, that those, who have stood forward so nobly to vindicate the national character from the guilt of sanctioning either the continuance or the renewal of the slave trade, should suffer a society to languish, for want of pecuniary support, on whose vigilance and exertions, we have no hesitation in saying, it mainly depends, not only whether our policy in respect to Africa shall be generally adopted by other nations, but whether our own abolition- laws shall be any thing more than a dead letter." See The Annual Reports of the African Institution; and the reviews of these reports in the Christian Observer and the Edinburgh Review. (q)

**INSTRUMENTS.** See Arithmetic, Astronomy, Barometer, Burning Instruments, Dialling, Drawing Instruments, Coniometer, Graduation, Hyderometry, Kaleidoscope, Microscope, Microscope, Music, Optics, Surgery, Telescope, Thermometer, and various other articles in our Work.

**ASSURANCE, or Assurance, in mercantile concerns, is a contract or engagement, by which one party becomes bound, for a specified sum, to insure during a limited time, the property of another against cer- tain risks to which it is peculiarly exposed.

The party who engages to indemnify for the loss that may be sustained, is called the **insurer, or Underwriter:** the compensation paid for the risk, the **premium; and** the document containing the obligation, the **policy.**

Goods insured are said to be covered, when not only their value, but the premium and other charges are in- sured. The term **average,** of which there are two kinds, is applied to goods insured against sea risk: **General average,** is a proportionable contribution paid by all the proprietors of a ship and cargo, for losses incurred with a view to guard against a total shipwreck; and **particular average,** is a contribution for such losses as may arise from ordinary accidents at sea, and is payable by the proprietors of the articles which suffer the damage. In computing **general average** for masts, rigging, &c. cut away for the security of the ship and cargo, it is usual to deduct a third of the expense of refitting, as the new articles may in general be con- sidered so much better than the old; but goods thrown overboard are estimated at the value they would have brought at the place of destination. When a ship, cargo, and freight, are fully insured, the underwriters are responsible for general and particular averages.

During a period of war, when there is a risk of capture,
When interest is calculated on a debt, discharged by partial payments, it is reckoned on the several sums due, from the time of the preceding to that of the last payment. This is done most conveniently by multiplying the original sum, and each successive balance, in order, by the number of days intervening between the times of payment, and then dividing the amount of the several products by 7300. The quotient is the interest at 5 per cent.

Ex. A bill of £625, due March 2, was paid up in the following manner: April 10, £182; June 8, £25; August 21, £96; and the balance, Dec. 5; what interest was due at 5 per cent.

<table>
<thead>
<tr>
<th>Date</th>
<th>Amount Due</th>
<th>Paid</th>
<th>Balance</th>
</tr>
</thead>
<tbody>
<tr>
<td>March 2</td>
<td>£625</td>
<td></td>
<td></td>
</tr>
<tr>
<td>April 10</td>
<td>£182</td>
<td>£182</td>
<td>£443</td>
</tr>
<tr>
<td>June 8</td>
<td>£25</td>
<td></td>
<td>£468</td>
</tr>
<tr>
<td>Aug. 21</td>
<td>£96</td>
<td></td>
<td>£372</td>
</tr>
<tr>
<td>Dec. 5</td>
<td>£106</td>
<td></td>
<td>£366</td>
</tr>
</tbody>
</table>

Then, the interest at 5 per cent. is £8 8s. 0½d.

In computing interest on accounts current, or cash accounts, the sums on the debtor and creditor side of the account are added and subtracted, in the order of their dates as they fall due; the several balances are then multiplied by the days as formerly, and if the balance be sometimes due to one party, and sometimes to the other, the products are extended in separate columns.

II. Compound Interest.

Let the amount of £1 for a year, or $1 + r$, be represented by $E$; then, since £1 is to its amounts for a year, as any other sum is to its amount for the same time,

\[ 1 : R : : R : R^2 \]

the amount of £1 for 2 years.

Also $1 : R^2 : : R : R^3 : : \ldots \ldots \ldots \ldots : R^t$.

Hence, it is obvious that $R^t$ is the amount of £1 for $t$ years. If the amount of $P$ pounds, for a year, be denoted by $A$, we obtain

\[ A = PR^t \]

\[ t = \frac{\log A - \log P}{\log R} \]

\[ R = \left( \frac{A}{P} \right)^{\frac{1}{t}} \]

The quantity $P$, or the sum which, laid out at compound interest during $t$ years, would amount to $A$, is sometimes called the present value of $A$. Thus, $R^t$ being the amount of £1 for $t$ years, £1 is the present-value of $R^t$ for the same time. Since it has been already shown that $P = \frac{A}{R^t}$, if $A$ be unity, or £1, we obtain

\[ P = \frac{1}{R^t} \]

Hence the present value of £1 for any time $t$, is the reciprocal of the amount of £1 for the same time.

Calculations connected with compound interest are usually performed by help of tables, containing the amount and present value of £1 for the requisite number of years. (A)

INTERMITTING, or RECIPROCATING SPRINGS. See HYDRODYNAMICS, vol. xi. p. 486.
INTERPOLATION is a branch of mathematical analysis, that treats of the methods by which, when a series of quantities succeeding each other, and formed according to some determinate law, are given, others subject to the same law may be interpolated between them.

Thus, to take a simple instance, the given quantities may be the cube roots of the numbers 2, 3, 5, 6, 7, and it may be required to find from these, by interpolation, the cube root of the number 4. Again, the given quantities may be the logarithms of any series of numbers, 2, 4, 6, 8, 10, &c., and it may be required to find the logarithms of the intermediate numbers 3, 5, 7, 9, &c. Or the given quantities may be the place of some celestial phenomenon, a comet for instance, at midnight, on four successive days, to find its place at any proposed time on any one of these days. Or, taking one example more, having given the expansive force of steam at certain temperatures; by interpolation, its expansive force at any temperatures intermediate between those, or a little greater or less may be found.

From these examples, it will easily be understood that the theory of interpolation must be of great practical importance, not only in pure mathematics, but also in astronomy and every branch of physics, in which the result of a series of experiments can be expressed by numbers.

The method of interpolation is altogether a branch of modern mathematics. It appears to have been for the first time employed by Henry Briggs, the ingenious improver of logarithms, in the construction of these numbers. (Hutton's Math. Tables, Introd. p. 69.) This was before the year 1694. Dr. Wallis, by interpolation, and a most happy application of the method of induction, found a remarkable expression for the area of a circle, (see his Arithmetica Infinitorum, 1655), and soon afterwards, Gabriel Mouton, an astronomer of Lyons, applied the theory to the construction of astronomical tables; he had, however, proposed to himself a problem which he could not resolve, and he gives the honour of the solution to his friend Regnault, Mouton's labours appeared in a book of observations on the diameters of the sun and moon, published in 1670.

The first general solution of the problem of interpolation was given by Sir Isaac Newton, but without demonstration, in his Principia, lib. iii. lem. 5. He afterwards gave a solution, with a demonstration, in his Methodus Differentialis, a small tract, which was published along with others, by W. Jones, the author of Synopsis Palmariorum Mathematicorum. The problem has since been discussed by every writer on the theory of differences, and series, and particularly by Mr. J. Stirling, in his Methodus Differentialis, sive Tractatus de Summatione et Interpolatione Serierum Infinitiorum, published in 1753. The principal works on this branch of mathematics, we believe, are contained in the following list.

Briggs, Arithmetica Logarithmica, Lond. 1624.
—— Trigonometria Britannica, Gouda, 1633.
Wallis, Arithmetica Infinitorum, Oxon. 1656.
Mouton, Observationes Diametrorum Sole et Lunae Apparentium, &c. Lugd. 1670.
Newton, Principia, lib. iii. lem. 5. Lond. 1687.
—— Methodus Differentialis (Opuscula), 1723.
Cotes, Canonisticum, sive Constructio Tab. per Differentias.

169. Herman, Phoronum, (Appendix,) Amst. 1716.
Craig, De Calculo Fluenteum, Lond. 1718.
Stirling, Methodus Differentialis, Lond. 1753.
Delambre, Mem. of the Acad. of Turin, 1790-1, p. 143.
Emerson, The Differential Method, Lond. 1767.
La Place, Mem. de l'Acad. Par. 1779.
—— Theorie Analytique des Probabilites, (p. 13.)
1814.

THE THEORY OF INTERPOLATION.

Let x and y be two variable quantities, having some Theory of determinate relation to each other, so that y may be interpo-
what is called a function of x. (See Fluxions, Art. 2, also the word Function.) If the form of the function be known, we can find the value of y, corresponding to any value of x whatever. For example, let the relation between x and y be such, that

\[ y = 3 + x + 2x^2; \]

then, when \( x = 0 \), we have \( y = 3 \), when \( x = 1 \), \( y = 6 \),
when \( x = 2 \), \( y = 13 \), and so on, as is shewn in the two
following sets of corresponding values.

\[
\begin{align*}
    x &= 0, 1, 2, 3, 4, 5, \ldots \\
    y &= 3, 6, 12, 24, 39, 58, \ldots
\end{align*}
\]

The values of y being thus formed all according to the same law, they constitute a regular series, and the corresponding values of x are the indices of the terms, that is, they shew their place, or distance from the beginning of the series. When a series is formed in this manner, by substituting successive values of \( x \) in \( y \), some function of \( x \), that function is called the general term of the series, it is analogous to the equation of a curve, and it serves to characterize the series, and to distinguish it from all others. Thus, as from the general term \[ y = \frac{(x + 1)(x + 2)}{2}, \] we get these corresponding values of \( x \) and \( y \):

\[
\begin{align*}
    x &= 0, 1, 2, 3, 4, 5, \ldots \\
    y &= 1, 3, 6, 10, 15, 21, \ldots
\end{align*}
\]

so, on the other hand, when this last series is put under this form

\[
\frac{1}{2} \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6
\]

we may infer that its general term is \( \frac{(x + 1)(x + 2)}{2} \); and that it can be no other expression.

It is easy to conceive that between every two adjoining terms of a series formed in this way, there may be any number of others interpolated, forming, upon the
whole, a series of the same nature as before, but consisting of more terms. Thus, in the series 1, 3, 6, 10, &c. of which the general term is \((x + 1) \frac{(x + 2)}{2}\), we may interpose three terms between every adjoining two, by making \(x = \frac{3}{2}, \frac{5}{2}, \frac{7}{2}\), also \(= 1, 1, 1\), &c. The terms of the series and their indices will then be

\[
x = 0, \frac{3}{2}, \frac{5}{2}, \frac{7}{2}, 1, 1, 1, &c.
y = 1, \frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \frac{7}{2}, \frac{9}{2}, 1, &c.
\]

When new terms are thus interposed between the terms of a given series, they are said to be interpolated.

If the law of formation, or general term of a series be given, there is no difficulty in interpolating any term, of which the index is given: however, in the application of this theory, it becomes necessary, that the general term is unknown, and only some particular values of it are given, by which it is to be found, or at least some approximation to it.

As the general term and its index are perfectly analogous to the ordinate and abscissa of a curve, the analytical problem to be resolved is manifestly the same as this geometrical one: Having given a determinate number of ordinates and the corresponding abscissæ, to find the equation of the curve; or to describe a curve through a certain number of given points. It was under this form that Newton first proposed and resolved the problem.

Let \(P^0, P^1, P^2, P^3, P^4, P^5\), &c. (in the annexed Figure) be the given ordinates, or particular values of the general term \(y\), which may stand either at equal or unequal distances from each other, the positive values \(P^0, P^1, P^2, &c.\) being supposed to lie on one side of the axis \(AB\), and the negative values \(P^4, P^5, P^6, &c.\) on the other; and let \(AP^0, AP^1, &c.\) be the given corresponding abscissæ, or particular values of the variable \(x\). Also let \(PQ = y\) be any indefinite ordinate, or term to be interpolated, and \(AP = x\) the corresponding abscissa, or variable index of that term, and, lastly, let \(CDE\) be the curve, passing through the tops of all the ordinates. The thing to be done is, to express \(y\) in terms of \(x\), or to find the nature of the curve.

If there be no datum, in addition to the condition, that the curve pass through the given points \(Q^0, Q^1, Q^2, &c.\) the problem is manifestly indeterminate, because, by varying the species, any number of curves may be conceived to pass through the given points. However, in the applications, the ordinates are in general near each other, the distances between them not very unequal, and the curve is known to have no considerable inflection between adjacent ordinates. Under these circumstances, we may assume that between \(P^0, P^1, P^2, &c.\) any two adjacent given ordinates, the indefinite ordinate \(y = PQ\) may be expressed by a series composed of the powers of the abscissa \(P^0, P^1, &c.\), thus,

\[
y = a + b \times (P^0) + c \times (P^0)^2 + d \times (P^0)^3 + &c.
\]

the quantities \(a, b, c, &c.\) being supposed constant; and as the series will converge, because \(P^0\) is small, a few terms at the beginning will be a near enough approximation to its value: Or, since \(AP = x\) is equal to \(AP^0 + P^0\), therefore, \(P^0P^1 = x - AP\). Substituting now this last quantity instead of \(P^0\), and remarking that \(AP^0\) is a given quantity, by hypothesis, we shall have

\[
y = A + Bx + Cx^2 + Dx^3 + &c.
\]

\(A, B, C, &c.\) being put for constant quantities: Curves having their equation of this form are called parabolic, from its analogy with the equation of the common parabola.

This expression for the ordinate \(y\) in the geometrical problem, is, considered analytically, the general term of the series to be interpolated, or at least, an approximation to it, which will be sufficiently near in the ordinary cases to which interpolation is applied.

The form of the expression for the ordinate or general term being settled, we are now to find the constant coefficients \(A, B, C, D, &c.\)

Let the given terms, or values of \(y\), which in the curve are represented by the ordinates \(P^0, P^1, P^2, P^3, &c.\) be denoted by the symbols

\[
y_0, y_1, y_2, y_3, &c.
\]

and their indices, or the corresponding values of \(x\), which in the curve are the abscissæ \(AP^0, AP^1, AP^2, &c.\) by

\[
x_0, x_1, x_2, x_3, &c.
\]

since the general equation

\[
y = A + Bx + Cx^2 + Dx^3 + &c.
\]

holds true for every pair of corresponding values of \(y\) and \(x\) we have, by substituting in it \(y_0\) and \(x_0\), then \(y_1, x_1, \&c.

\[
y_0 = A + Bx_0 + Cx_0^2 + Dx_0^3 + &c.
y_1 = A + Bx_1 + Cx_1^2 + Dx_1^3 + &c.
y_2 = A + Bx_2 + Cx_2^2 + Dx_2^3 + &c.
y_3 = A + Bx_3 + Cx_3^2 + Dx_3^3 + &c.
\]

The number of these equations must be equal to the number of constant, but indeterminate coefficients \(A, B, C, D, &c.\), and as only the simple powers of these enter the equations, they may be all determined as follows.

By subtracting successively the first equation from the second, then the second from the third, and so on; and afterwards dividing the respective results by \(x_2 - x_0, x_3 - x_1, x_4 - x_2, &c.\) we obtain

\[
y_1 - y_0 = B + C(x_1 + x_0) + D(x_1^2 + x_1x_0 + x_0^2) + &c.
x_1 - x_0
\]

\[
y_2 - y_1 = B + C(x_2 + x_1) + D(x_2^2 + x_2x_1 + x_1^2) + &c.
x_2 - x_1
\]

\[
y_3 - y_2 = B + C(x_3 + x_2) + D(x_3^2 + x_3x_2 + x_2^2) + &c.
x_3 - x_2
\]

Putting now, in order to abridge,

\[
y_1 - y_0 = Y_0, y_2 - y_1 = Y_1, &c.
x_0 \quad x_1 \quad x_2
\]

we have these equations
The general expression we have found for \( y \) admits of another very elegant form, due to Lagrange, and which has the advantage of being well adapted to logarithmic calculation. If, in the expression for \( Y_o' \), we substitute the values of \( Y_1 \) and \( Y_0 \), we get

\[
y'(x) = \frac{Y_1'(x-x_0) + Y_2'(x-x_1) + \ldots + Y'_n(x-x_{n-1})}{(x-x_0)(x-x_1)(x-x_2)\ldots(x-x_{n-1})}
\]

which, by putting \( a, b, \gamma \), for the co-efficients of \( y_0', y_1', \) and \( y_n' \), takes the form

\[
a'y_0 + b'y_1 + \gamma y_n'
\]

In like manner \( Y_1', Y_2', \) and \( Y_n' \) are found to be of the form

\[
a'y_0 + b'y_1 + \gamma y_n + \beta y_2 + \ldots + \delta y_n
\]

Again, if these results be put in the expression for \( Y_0' \), it will take the form

\[
a'y_0 + b'y_1 + \gamma y_n + \beta y_2 + \ldots + k'y_n
\]

where \( a, b, c, \ldots, k \) are co-efficients depending on the quantities \( x_0, x_1, \ldots, x_n, \) and entirely independent of \( y_0, y_1, \ldots, y_n \). The values of \( a, b, c, \ldots, k \) may be easily determined for any particular case, by following the above process of substitution; but they may also be discovered, as it were, by inspection, if we recollect that, when the indefinite abscissa \( x \) increases gradually from \( x_0 \) (or 0) becomes \( x_1 \), then the indefinite ordinate \( y \) becomes \( Y_0 \). In this case, all the terms after the first ought to vanish; so that \( a = 1, b = 0, \ldots, c = 0 \). But the quantities \( b, c, d, \ldots, k \) can only vanish by reason of some common factor becoming 0. Now, we know that, in this particular case, \( x = x_0 \); therefore \( x = x_0 \) must be a factor of all the co-efficients, except \( a \). In like manner, it will appear that \( x = x_n \) must be a factor of all the co-efficients, except \( b \); also, that \( x = x^2 \) must be a factor of all, except \( c \), and so on. This putting \( A \) to denote some constant quantity, we must have

\[
a = A \times (x-x_0)(x-x_1)\ldots(x-x_{n-1})
\]

and supposing that \( x \) becomes \( x_n \) so that \( a = 1 \),

\[
b = A \times (x-x_0)(x-x_1)\ldots(x-x_n)
\]

and hence

\[
A = \frac{1}{(x-x_0)(x-x_1)\ldots(x-x_n)}
\]

and

\[
A = \frac{(x-x_0)(x-x_1)\ldots(x-x_n)}{(x-x_0)(x-x_1)\ldots(x-x_n)}
\]

In like manner,

\[
b = \frac{(x-x_0)(x-x_1)\ldots(x-x_n)}{(x-x_0)(x-x_1)\ldots(x-x_n)}
\]

for none of the co-efficients can contain any power of \( x \) higher than \( n-1 \). Substituting, therefore, these values, we get

\[
y = \frac{(x-x_0)(x-x_1)\ldots(x-x_n)}{(x-x_0)(x-x_1)\ldots(x-x_n)} \cdot \frac{(x-x_0)(x-x_1)\ldots(x-x_n)}{(x-x_0)(x-x_1)\ldots(x-x_n)}
\]

\[
+ \frac{(x-x_0)(x-x_1)\ldots(x-x_n)}{(x-x_0)(x-x_1)\ldots(x-x_n)} \cdot \frac{(x-x_0)(x-x_1)\ldots(x-x_n)}{(x-x_0)(x-x_1)\ldots(x-x_n)}
\]

\[
+ \&c.
\]
The Theory of Interpolation.

Each term of which may be easily calculated by means of logarithms.

We have now resolved the problem in its most general form, and have found two different expressions for the indefinite ordinate \( y \); it is, however, desirable, when the nature of the case will admit, to have the ordinates, or particular values of \( y \), at equal distances, and then the differences \( x_1 - x_0, x_2 - x_1, \ldots \), &c. are all equal.

In this case, let \( y_0, y_1, y_2, \ldots, y_n \), &c. be taken in their order, and then the difference of each of these differences, and so on, as in the adjoining table, where \( a_0 \) is the difference between \( y_0 \) and \( y_1 \), and \( a_1 \) is the difference between \( y_1 \) and \( y_2 \), and \( a_2 \), \( a_3 \), &c.

and so on; and, similarly, \( \beta_0 \) is the difference between \( a_0 \) and \( a_1 \), and \( \gamma_0 \) is the difference between \( a_1 \) and \( a_2 \), &c.

If we now put \( h \) for the equal differences \( x_i - x_{i-1} \), &c. it is evident that

\[
Y_i = \frac{a_0}{h}, \quad Y_i = \frac{a_1}{h}, \quad Y_2 = \frac{a_2}{h}, \quad Y_1 = \frac{a_1}{h}, \quad \text{&c.}
\]

\[
Y_i = \frac{\beta_0}{2h}, \quad Y_i = \frac{\beta_1}{2h}, \quad Y_2 = \frac{\beta_2}{2h}, \quad \text{&c.}
\]

\[
Y_i = \frac{\gamma_0}{2.3h^3}, \quad Y_i = \frac{\gamma_1}{2.3h^3}, \quad \text{&c.}
\]

\[
Y_i = \frac{2}{2.3.4h^4}, \quad \text{&c.}
\]

These values of \( Y_0, Y_1, Y_2, \ldots, Y_n \), &c. being substituted in formula (1), it becomes

\[
y = y_0 + \frac{x-x_0}{h} a_0 + \frac{(x-x_0)(x-x_1)}{1.2h^2} \beta_0 + \frac{(x-x_0)(x-x_1)(x-x_2)}{1.2.3h^3} \gamma_0 + \text{&c.}
\]

Here the law of continuation is evident.

If we suppose the abcissa \( x \) to be at \( P_0 \), in the above figure, the bottom of \( P_0 O P_1 \), the first ordinate, then \( x_1 = x_0, x_2 = x_0 + h, \ldots \), &c.; and the last expression may be put under this form,

\[
y = y_0 + \frac{x-x_0}{h} a_0 + \frac{x-x_0}{h} \left( \frac{x-x_1}{h} \right) \beta_0 + \frac{x-x_0}{h} \left( \frac{x-x_1}{h} \right) \left( \frac{x-x_2}{h} \right) \gamma_0 + \text{&c.}
\]

We have hitherto employed only the notation of the Elements of Algebra; but there is one particularly well suited to this branch of analysis, which is in common use, when the quantities which enter into an investigation are the successive differences of the terms of a series.

To understand the nature of this notation, let \( u \) be some variable quantity, and \( u_1, u_2, u_3, \ldots, u_n \), a series of consecutive values, which it acquires, either by varying itself, or else, in consequence of a change in the values of some variable quantity on which it depends:

(For instance, \( u \) may be the abcissa of a curve, or else the ordinates.) Then, \( x - u \) is expressed by the symbol \( \Delta u \), the Greek letter \( \Delta \) being prefixed, not as a co-efficient, but as a characteristic, to denote the difference between two consecutive values of the variable \( u \). In like manner,

\[
u_1 - u_0 = \Delta u_1,
\]

and in general,

\[
u_n - u_{n-1} = \Delta u_n - 1.
\]

If the function \( u \) vary by equal increments, the differences \( \Delta u, \Delta u_1, \Delta u_2, \ldots, \) &c. will be all equal; but if it does not, these constitute a new series of quantities, the differences of which may be expressed by the same notation, thus:

\[
\Delta u - \Delta u_1 = \Delta u_1 - \Delta u_2 = \ldots = \Delta u_{n-1} = \Delta u_n - 1;
\]

and here the figure placed over the \( \Delta \) is to be understood, not as the index of a second power, but as indicating a term of a second order of differences, originating from the variable function \( u \).

In like manner, by taking the differences between the terms of the second order of differences, a third order is formed, which are expressed thus,

\[
\Delta^2 u - \Delta^2 u_1 = \Delta^2 u_1 - \Delta^2 u_2 = \ldots = \Delta^2 u_{n-1} = \Delta^2 u_n - 1;
\]

and so on, to differences of a fourth and higher orders.

By attending to the manner in which the quantities

\[
x_0, x_1, x_2, x_3, \ldots, \text{&c.}
\]

\[
\beta_0, \beta_1, \beta_2, \ldots, \text{&c.}
\]

\[
\gamma_0, \gamma_1, \gamma_2, \ldots, \text{&c.}
\]

\[
\delta_0, \delta_1, \text{&c.}
\]

have been formed from the series

\[
y_0, y_1, y_2, y_3, \ldots, \text{&c.}
\]

the successive values of the function \( y \), it will immediately appear that

\[
x_0 = \Delta y_0, \quad x_1 = \Delta y_1, \quad x_2 = \Delta y_2, \quad \text{&c.}
\]

\[
\beta_0 = \Delta^2 y_0, \quad \beta_1 = \Delta^2 y_1, \quad \beta_2 = \Delta^2 y_2, \quad \text{&c.}
\]

\[
\gamma_0 = \Delta^3 y_0, \quad \gamma_1 = \Delta^3 y_1, \quad \gamma_2 = \Delta^3 y_2, \quad \text{&c.}
\]

\[
\delta_0 = \Delta^4 y_0, \quad \text{&c.}
\]

so that, by employing the notation of differences to the last general expression in both of its forms, we shall have

\[
y = y_0 + \frac{x-x_0}{h} \Delta y_0 + \frac{(x-x_0)(x-x_1)}{1.2h^2} \Delta^2 y_0 + \frac{(x-x_0)(x-x_1)(x-x_2)}{1.2.3h^3} \Delta^3 y_0 + \text{&c.}
\]

also, supposing the abcissa to begin at the bottom of the first ordinate,

\[
y = y_0 + \frac{1}{h} x \Delta y_0 + \frac{1}{1.2} \frac{x}{h} \left( \frac{x}{h} - 1 \right) \Delta^2 y_0 + \frac{1}{1.2.3} \frac{x}{h} \left( \frac{x}{h} - 1 \right) \left( \frac{x}{h} - 2 \right) \Delta^3 y_0 + \text{&c.}
\]
The law of this series is evident, its terms being manifestly the first of the successive orders of differences multiplied by the co-efficients of a binomial raised to the power \( \frac{x}{h} \).

There is another form under which this expression may be put, which is at once concise and elegant. The symbol \( \Delta y \), having been used to denote \( y_1 - y_0 \), the difference between two successive values of \( y \), let us now put \( \Delta y_0 \) to denote \( y - y_0 \), which is the whole increment that the function \( y \) receives by changing from \( y_0 \), its first particular value, to its present magnitude. The foregoing expression may now be put under the form

\[
1 + \frac{\Delta y_0}{x} = \left(1 + \frac{\Delta y_0}{h}\right)^x \quad \quad (5)
\]

observing that in the development of the second member by the binomial theorem, we must transfer the exponents of the powers of the quantity \( \Delta y_0 \) to characteristic \( \Delta \); that is, we must write \( \Delta y_0 \) for \( (\Delta y_0)^1 \), and \( \Delta^2 y_0 \) for \( (\Delta y_0)^2 \), and so on.

**APPLICATION OF THE THEORY.**

We shall give some examples of the application of the theory of interpolation.

**Example 1st.**

Ex. 1. Let it be required to find the common logarithm of 3.1415926536, by means of a table containing the logarithms of numbers from 1 to 1000 to 10 decimals.

In this case, we may regard the numbers as the successive values of the abscissa \( x \), and their logarithms, as the corresponding values of the ordinate \( y \). If we take

\[
x_0 = 3.14, \quad x_1 = 3.15, \quad x_2 = 3.16, \quad x_3 = 3.17, \quad x_4 = 3.18,
\]

we shall have the following corresponding values of \( y \), and their differences:

<table>
<thead>
<tr>
<th>Particular Values of ( y )</th>
<th>1st Diff.</th>
<th>2nd Diff.</th>
<th>3rd Diff.</th>
<th>4th Diff.</th>
</tr>
</thead>
<tbody>
<tr>
<td>( y_0 = 0.40692991401 )</td>
<td>( y_1 = 0.19331025538 )</td>
<td>( y_2 = 0.4966870826 )</td>
<td>( y_3 = 0.5080392626 )</td>
<td>( y_4 = 0.50944271200 )</td>
</tr>
</tbody>
</table>

Here it appears, that the differences of the successive orders are alternately positive and negative; and that

\[
\Delta y_0 = +0.00013809057
\]

\[
\Delta^2 y_0 = -0.0000003760
\]

\[
\Delta^3 y_0 = +0.00000000003
\]

We have also \( x = 3.1415926536 \)

\[
x_0 = x_0 = 0.00013809057
\]

\[
x_1 = x_0 = 0.0000003760
\]

\[
x_2 = x_0 = 0.00000000003
\]

\[
\Delta y_0 = +0.00013809057
\]

These values being substituted in the formulae:

\[
y = y_0 + \frac{x - x_0}{1.\, h} \Delta y_0 + \frac{(x - x_0)(x - x_0)}{1.\, h^2} \Delta^2 y_0 + \frac{(x - x_0)(x - x_0)(x - x_0)}{1.\, h^3} \Delta^3 y_0 + \&c.
\]

it will be found, after executing the arithmetical operations, that

\[y = \log 3.1415926536 = 0.4071498726.\]

This is not the easiest way of finding the logarithm of a number consisting of a great many figures; but it serves very well as an example of the interpolation of a term in a series.

Ex. 2. Let it be required to find the moon's longitude, Nov. 18, 1817, at 16° 22' 16", having given, 2d. from the Nautical Almanac, 1817.

<table>
<thead>
<tr>
<th>Moon's Longitude.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nov. 18, Noon</td>
</tr>
<tr>
<td>Midnight</td>
</tr>
<tr>
<td>19, Noon</td>
</tr>
<tr>
<td>Midnight</td>
</tr>
</tbody>
</table>

Questions of this nature continually occur in practical astronomy. The tables give the calculated places of a phenomenon at equal intervals, and from these their place at some intermediate instant is to be found. From our general expression, \( (5) \) the rule for four calculated places is this:

Call \( y_0, y_1, y_2, y_3 \), four succeeding given places of the phenomenon at equal intervals of time, and \( h \) the common interval; put \( x \) for any indefinite intermediate time, reckoned from the instant for which the first place is given, and \( y \) for the corresponding place of the phenomenon; then

\[
y = y_0 + \frac{x}{h} \Delta y_0 + \frac{x}{1.\, h} \Delta^2 y_0 + \frac{x}{1.\, h^2} \Delta^3 y_0
\]

In the present example, \( h = 12 \) hours, and \( x = 16^\circ \text{-} 22' \), hence

\[
\frac{x}{h} = 1.36426, \quad \frac{x}{h} - 1 = 0.36426, \quad \frac{x}{h} - 2 = -0.03574.
\]

The particular values of \( y \) and their differences, are

<table>
<thead>
<tr>
<th>( y_0 = 11^\circ 26' 59&quot; 0' )</th>
<th>1st Diff.</th>
<th>2nd Diff.</th>
<th>3rd Diff.</th>
</tr>
</thead>
<tbody>
<tr>
<td>( y_1 = 0 )</td>
<td>0 ( \text{2} \text{.} \text{57} \text{.} 11 )</td>
<td>21911&quot;</td>
<td>-170&quot;</td>
</tr>
<tr>
<td>( y_2 = 0 )</td>
<td>0 ( \text{8} \text{.} \text{59} \text{.} 32 )</td>
<td>21741&quot;</td>
<td>-145</td>
</tr>
<tr>
<td>( y_3 = 0 )</td>
<td>0 ( \text{14} \text{.} \text{59} \text{.} 28 )</td>
<td>21596&quot;</td>
<td>25</td>
</tr>
</tbody>
</table>

Hence it appears, that

\[
\Delta y_0 = +21911, \quad \Delta^2 y_0 = -170, \quad \Delta^3 y_0 = +25.
\]

The first term of the value of \( y \), is \( 11^\circ 26' 52" 0' \) the second, \( +29892" \) the third, \( -42.4" \) the fourth, \( -1.3" \)

\[29848 = 0 \, 8 \, 17 \, 28\]

Moon's Long. Nov. 18\(^{th}\) 16\(^{th}\) 22\(^{m}\); 16\(^{h}\) is \( 0 \) 5 9 28

Ex. 3. The calculated distances of the moon's centre from the star Aldebaran, are

1817. Nov. 1. Noon 53" 20' 16"
Midnight 50 33 47
Nov. 2. Noon 65 52 58
Midnight 72 18 10

Find, by interpolation, the distances at the 11th, 16th, and 19th hour of the first interval.

As in the last example, let \( y_0, y_1, y_2, y_3 \), denote the given distances, and \( y \), the required distance at each in-
**INTERPOLATION.**

Example 4th.

Given a correct distance from the sun on the four following days at 12 at night, to find its distance Dec. 20.

| Dec. 12 | Distance | 301 |
| Dec. 21 | 620 |
| Dec. 24 | 715 |
| Dec. 26 | 772 |

This case, in which the intervals between the given successive values are unequal, may serve to exemplify formula (2). By employing the usual notation, and reckoning x the time from Dec. 12, we have

\[ x_0 = 0, \quad y_0 = 301, \]
\[ x_1 = 9, \quad y_1 = 620, \]
\[ x_2 = 12, \quad y_2 = 715, \]
\[ x_3 = 14, \quad y_3 = 772, \]
\[ x = 8, \quad y \text{ is required.} \]

From the values of x we get

\[ x - x_0 = 8, \quad x - x_1 = 9, \quad x - x_2 = 12, \quad x - x_3 = 14, \]
\[ x - x_0 = 9, \quad x - x_1 = 10, \quad x - x_2 = 13, \quad x - x_3 = 15, \]
\[ x - x_0 = 10, \quad x - x_1 = 11, \quad x - x_2 = 14, \quad x - x_3 = 16, \]
\[ x - x_0 = 12, \quad x - x_1 = 13, \quad x - x_2 = 15, \quad x - x_3 = 17. \]

These differences, and the values of y being substituted in the expression

\[ y = \frac{(x - x_1)(x - x_2)(x - x_3)}{(x_0 - x_1)(x_0 - x_2)(x_0 - x_3)} y_0 + \frac{(x - x_0)(x - x_2)(x - x_3)}{(x_1 - x_0)(x_1 - x_2)(x_1 - x_3)} y_1 + \frac{(x - x_0)(x - x_1)(x - x_3)}{(x_2 - x_0)(x_2 - x_1)(x_2 - x_3)} y_2, \]

it becomes after abbreviation,

\[ y = \frac{1}{63} \times 301 + \frac{64}{45} \times 620 - \frac{2}{3} \times 715 + \frac{586.3}{772}, \]

or y = 586.3, the distance of the comet from the sun, Dec. 20.

Ex. 5. In the year 1500, Bernard Walther at Nu- uemberg observed the chord of the sun’s distance from the zenith, by a large parallactic instrument of Ptol- emy, as follows.

June 2. O.S. 45467 June 12. O.S. 44883
8. . . . . 44075 15. . . . . 44090
9. . . . . 44034

From these observations, it is required to find the true instant of the summer solstice.

In this example, we might make the given chords the ordinates of a curve, and the corresponding times, reckoned from some fixed instant, the abscissae; we would then have five ordinates, and their abscissae, to find the abscissa corresponding to the least ordinate; so that the problem requires for its solution, besides the theory of Interpolation, that of maxima et minima; which is given, Fluxions, Art. 61–60.

If we employ the five given ordinates at once, the function to be made a minimum will be of the fourth degree, in respect of the variable x, and the problem, in general, will lead to the solution of a cubic equation. To avoid this, it will be better to take only three of the five; and then the curve will be a common parabola, having its axis perpendicular to the abscissa x; in fact, the problem, from its nature, admits of this simplification, for it is evident, that the values of y must be equal at equal distances from its least value, which is a property of the parabola. As there are five given ordinates, there may be various sets of three formed from them, and those may be selected which are most suitable, and a mean taken among the results.

Let us now suppose that x and y are any indefinite values of the co-ordinates. Then, the given values of the abscissa being x_1, x_2, x_3, and of the ordinates y_0, y_1, y_2, the general formula, in the case of three ordinates, gives

\[ y = \frac{(x - x_1)(x - x_2)}{(x_0 - x_1)(x_0 - x_2)} y_0 + \frac{(x - x_0)(x - x_2)}{(x_1 - x_0)(x_1 - x_2)} y_1 + \frac{(x - x_0)(x - x_1)}{(x_2 - x_0)(x_2 - x_1)} y_2, \]

which, by taking away the denominators, and developing the terms, so that they may be arranged according to the powers of x, becomes

\[ A y = \left[(x - x_2) y_0 - (x_0 - x_2) y_1 + (x_0 - x_1) y_2\right] x - \left[(x_1 - x_2) y_0 - (x_0 - x_2) y_1 + (x_0 - x_1) y_2\right] x^2 + C. \]

And here, A and C denote constant quantities made up of the particular values of x and y.

Now as y_0, and consequently A y, is to be a minimum, the fluxion of the second member of this equation, after the terms are divided by the fluxion of x, must be = 0. (Fluxions, Art. 63.) Hence, taking the fluxions, (Rule A, Art. 26.) and transposing, &c. we get

\[ x^2 y_0 = \left[(x_2 - x_1) y_0 - (x_0 - x_2) y_1 + (x_0 - x_1) y_2\right] x - \left[(x_1 - x_2) y_0 - (x_0 - x_2) y_1 + (x_0 - x_1) y_2\right] x^2 + C. \]
The formula, by which we have determined the solstices, will equally apply to other cases, in which the values of \( y \) at equal distances from its maximum or minimum value are equal.

We shall have occasion to advert to this subject again under the article Series. (E)

**INTerval in Music.** is the distance of two sounds, as to acuteness and graveness; what, however, is here called distance, is, as Dr. Robison has observed, purely figurative and analogical, and not real: but the analogy is very good, and the observation of it has led to the discovery of precise measures of the intervals between defined or musical sounds. These last are such, as preserve for a sufficient period of observation, or comparison with other sounds, the same identical pitch, or degree of acuteness. The multiplied and greatly varied experiments of philosophers have shewn, that this stability of pitch is accompanied by, and indeed occasioned by the pulses or vibrations of some elastic body, repeated at very quick and exactly equal intervals of time.

From the pitches of two given sounds, or the numbers of their Vibrations (see that article and Concert Pitch,) in a given short interval of time, as one second for instance, the interval between them is therefore to be somehow measured; but it will be found, that this cannot be done by considering the vibrations as lineal, and taking their simple difference by subtraction as the measure of the interval, because in this way all sorts of absurdities or disagreements with the most simple and obvious experiments, would follow in different cases.

But if we consider each particular pitch or velocity of vibration to be a logarithm, or measure of a ratio, instead of a lineal dimension, or mere numeral quantity, we shall then find, that the differences of these logarithms, which are themselves also logarithms, naturally and correctly represent the intervals of sounds. Every interval, therefore, may be considered as the modules or unit of a particular logarithmic scale, as has been shewn under the articles BINARY, COMMON, and HYPERBOLIC LOGARITHMS; and every logarithm, of whatever species, as the measure or representation of some interval of sound.

Since the numbers of vibrations of simple elastic strings of equal magnitudes, densities, and tensions, are found to be in the direct ratio of their length, it follows, that the ratios of these lengths of vibrating strings are also correct representations of the intervals yielded by the vibrations of these strings. And this, although rather an unnatural and forced way of considering the measure, and effecting the calculation of musical intervals, was the earliest, and continued through several centuries to be the only mode which mathematical musicians had, of representing and calculating intervals; because in those days logarithms were unknown, and the intervals then known (even the Comma, having the ratio \( \frac{9}{8} \), the least of them) were too considerable in magnitude, to be used in the convenient or natural representation of other intervals.

But within a few years past, since the labours of the late Mr. Marmaduke Everard and others have brought to light and shewn the relations of several intervals very many times smaller than the comma, or least interval of the ancients, Mr. Farey has been enabled to adopt a notation, which in terms of three (at the most, and often of two,) of these very small intervals, is calculated in a correct and natural way without negative signs, (except in a few and unimportant instances,) to represent all musical intervals whatever, as has been shewn.
in our article Farey's Notation, and exemplified under
the names of all the intervals which have hitherto oc-
curred in our work.

Great as were the number of intervals, or rather the
numbers of names by which the numerous writers on
music had denominated them, prior to the appearance
of the Rev. Henry Liston's Essay on perfect Intonation,
as we have endeavoured to explain them in the pro-
gress of our work, the numbers of well-defined and
perhaps of useful intervals, are, by Mr. Liston's lab-
rours and discoveries, very greatly extended, even
to the number of 250 within the octave, as Mr. Farey
has recently shewn in a paper in the Philosophical
Magazine, vol. xl vi. p. 362, wherein he has sketched
out the principles of Nomenclature, by which each
one of these Listonian intervals may be clearly deno-
mated.

The Numerals major and minor, which practical
musicians use, as the common mode of expressing or
reckoning the intervals of the scale, viz. I, II, III,
4, 5, 6, 7, VIII, and VIII, furnish the sixteen gen-
eric terms; whence, by means also of the
specific terms Comma and Diesis variously com-
ounded, Mr. Farey proposes to distinguish each of these 220
intervals.

In practice, musicians use still more commonly an-
other mode of defining intervals, viz. by the Literals,
viz. F, C, G, D, A, E, B; which thus arranged, are
each at the distance of a true fifth (V) apart, except
and A, between which is a grave fifth (V), each
of these 7 literals being at times (successively from F
upwards) raised a chromatic half note or sharp (V),
which sometimes is of the value S, and sometimes
only; and at other times these literals (successively
from F downwards) are lowered a chromatic half note
or flat (S or D).

Besides which, Mr. Liston occasionally raises each of
these 7 literals, and sharpened or flattened notes, (in
the succession above named,) a major comma (c) or acute
(4) ; or lowers each of them, (in the reverse order,) a
major comma (c) or grave (4). And when occasion
requires, these sharps and the flats, together with the
acutes and the graces, are by Mr. Liston and Mr. Far-
ey respectively doubled, trebled, &c. (v, i; 3; 4;
bb, b, b, b, b, b, b, b); in connection with the lit-
erals in all their varieties of combinations; by which
means a literal notation is formed, comprehensive enough
for expressing each of the 220 notes above alluded to,
and even a much greater number, which are next to be
mentioned.

Mr. Liston's scale of 59 notes in the octave, tuned by
means of perfect 7ths, 11ths, and 17ths, as described
in pages 7, 44, and 45 of his Essay, and to which
the most extended of his Equal Harmonic Organs yet
made have been adapted, contains no doubly accented or
graved notes, and only four double sharps, viz. F, F,
G, and C, and two double flats, viz. B, and B; but
the principles of his toning process admit of being ex-
tended, as Mr. Farey has recently shewn, in the Philo-
osophical Magazine, vol. xl vi. p. 443.) to produce 612
notes in the octave, placed, as to acuteness and graveness,
nearly enough at equal distances from each other, to ad-
mit of being so considered, for all the common pur-
poses of harmonics, or musical calculations, and accord-
ing to the artificial commas (E's) of Mr. Farey's nota-
tion.

A Table of Listonian Intervals, extended, by Mr. Farey,
to a nearly equal Scale of 612 Notes in the Octave.

</table>

which contains each of the 612 notes above alluded to,
expressed in artificial commas above C, viz. 0, 1, 2, 3,
4, &c. to 612; and in literals, with their proper marks
or signatures, viz. C, B, B, B, B, B, B, &c. to c; for-
ming thus a more complete and systematic table of
musical intervals than was ever before communicated
to the public, or perhaps formed.

We have been enabled, by another arrangement of
the materials of this Tuning Table into thirteen divi-
sions, to bring it within the compass of our pages, and
are happy in the opportunity of thus presenting our
musical readers with it as an important acquisition to
the science of harmonics.
The above Table, is throughout divided into eight vertical columns, in the latter seven of which, the \textit{licitals}, in the order of consecutive fifths, are placed at the heads of each of the thirteen divisions of the Table. These divisions are made and arranged, according to the number of \textit{grave} and \textit{acute} marks in the signatures of the intervals, in the first column; the graves, decreasing in number, through the several divisions, from 6 to 0, and the acutes, increasing in number, through them, from 1 to 6.

In each division of the Table, the \textit{sharps}, in the first column, are first placed, in a decreasing series, to 0 sharp (or flat); and the \textit{flats} follow, in an increasing series, from 1. The numbers in the squares of the Table, are \textit{artificial commas}, of Fary, each one of these answering to the literal at the top of its column, with the signature annexed, which is set at the beginning of its line.

Thus, the first note in the Table, is to be read, \textit{F} six times acuted, containing 320 artificial commas, or schiasata, and wrote thus, $F^{6}$, or $320^{2}$. The first note of the seventh division, is to be read, \textit{F} five times sharpened, and marked $F^{5}$, or $467^{2}$. The last note in the Table is to be read, \textit{F} six times grave and once flattened, and marked $E^{6}$, or $95^{2}$, &c.

On examining the numbers of artificial commas in each horizontal line of the Table, the \textit{differences} of each adjacent note therein, proceeding from left to right, will be found to be, either $+36$, (answering to $V_{1}, = 3562 + 3 f + 31 m$) or, $- 254$; $(V_{11}, = - 4, = - 329$ $= 5 f$ $= 22 m)$: except, that in a rarer number of instances, this \textit{difference} will be found, either $+ 347$ $(V_{1}, = 3472 + 7 f + 30 m)$, or, $- 265$ ($= 4^{2} = 2652 + 5 f + 23 m$).

In like manner, on examining the \textit{differences} in the vertical columns of each division, from the top downwards, it will be found, that there are, \textit{alternately}, either $- 47$ (answering to $- S, = - 472$ $= f - 4 m$), but where the addition of an octave $(V_{8}, = 612x + 12 f + 53 m)$ becomes necessary; or, $- 36$, ($= 325$ $= f - 3 m$); so that the \textit{difference} between every alternate number, is, $- 83$ ($= - 8 - 3 = - 832 = 2 f - 7 m$), or, an octave different from this; except, that in the C column, in that line of each division where no \textit{sharp} or \textit{flat} occurs in the signature, these \textit{differences}...
are not alternately $\Sigma$ and $\varphi$, or $\varphi$ and $\Sigma$, but are both alike, or $\varphi$; and this sum is, $942 + 2f + 5m$; a curious
anomaly of the scale, which Mr. Farey has pointed out; and, in a note to p. 415, in his paper already quoted, has ascribed it to the practice of
turning both ways from C upwards to G and downwards to F, in forming the scale.

We shall now be enabled to give rules of very useful application, by which, any note being given, either by its literal designation, or in Mr. Farey's notation, or by its ratio of vibrating strings, either of the other two expressions for the same note may be quite correctly obtained, more than the artificial commas can show, which are approximate numbers.

1st. When the Literal designation of a Note is given.—It will be necessary to premise the following Table of the values of the literals, in the other two modes of notation, with the addition of the numerals in the last column, viz.

<table>
<thead>
<tr>
<th>x</th>
<th>f</th>
<th>m</th>

</tr>
</tbody>
</table>

It will also be necessary to bear in mind the following

designations, viz.

\[
\begin{align*}
&x^f + 110 + 11 - 4 + 1 - 1 \\
&\pm 40 + 2 + 1 + 2 - 3\end{align*}
\]

Rule. To the given literal note, or its proper octave, apply, as the signs indicate, the values of the given number of graves or of flats, and of pairs of sharps or of flats (x); and if there be an odd one in such, apply $\Sigma$ for it, and the resulting result will be had; either true, or a major comma (c) too great or too small, which the artificial commas in the great Table will show and detect.

For example, if $B^b$ be given, then, for $\Sigma$ and $m$, we have $555 + 11f + 48m$, $5 + (112 + 4m)$, $982 - 2f - 7m$, $472 - 4f - 4m$, equal to $802 - 8f + 44m$. For the indices of the primes in its ratio, we have $3 - 1 - 1 + 1 - 20 - 20 + 5$, $10 - 10 + 2 - 3$, $-3 + 3 + 1$,

equal to $6 - 16 - 8$, or $32$, the interval above C.

Again, if $B^g$ be given, then, as B must be taken an octave lower, we have $572 - f - 5m$, $2 + 83 + 2f + 7m$, $472 + f + 4m$, equal to $732 + 2f + 6m$; but 62 appearing to be the artificial comma, answering to this note in the large Table, we have $62 + 2f + 5m$ for the interval required above C; and $4 - 1 - 1 + 1 - 10 - 2 - 3$, $3 + 3 + 1 = 2$ (or $\Sigma$), is equal $17 - 2$

2d, When Farey's Notation of a Note is given.—Rule. Search through the great Table for the artificial commas, which answers to the number of 20 given, and take out the literal designation answering thereto, as above said.

The ratio will be found by the rule already given. For example, if $306 + 5f + 27m$ be given, on searching through the Table, we find, in the first line of its 7th division, that the note should be $D^g$. In order to try whether this be correct, on applying the first rule, we have $1043 + 2f + 9m$, $460 + 2f + 14m$, $306 + f + 27m$, which happens not to be the note given; but $B^g$, as will be seen from the last note in this division, and from the following process, viz. $555 + 11f + 48m$, $-490 - f - 21m$, $306 + 5f + 27m$, as given. For the ratio of the last interval, we have $3 - 1 - 1 - 30 + 6 + 9 = 77 + 5 + 8$.

3d, When the Ratio of a Note is given.—Rule. If the ratio is given in numbers, find their component primes by division, or $2$, or $3$, successively; then, from the Table and rule, in p. 275 of vol. ix. find the numbers of $m$, $2$, and $m$, and apply the 2d and 1st rules above, for finding and proving the literal designation.

After what has been done above, farther examples are, perhaps, unnecessary.

From the ratio of an interval above C of the tenor clif line, it is easy to deduce correctly its number of vibrations; from the circumstance of 240, the vibrations per 1/° of this C (see our article Concert Pitch), happening to be composed of the musical primes 2, 3, and 5, viz. $2^4 \times 3 \times 5$, or $4 + 1 + 1$.

Rule. From the constant indices of primes, $4 + 1 + 1$, deduct those of the given interval (or add them with contrary signs,) and the primes composing the number of vibrations will be had.

If, for example, the fourth of Mr. Farey's Temperament, in p. 273 of vol. ix. be given, viz. $357 + 7f + 9m$, whose ratio is $14 + 7 + 1$; we have

\[
\begin{align*}
&4 + 1 + 1 + 1 + 7 - 1, = 18 - 6 - 0, = 29
\end{align*}
\]

359, 59, 40, the vibrations per 1/°, which were required.

Intervals have been considered in our work, or are in the course of being so treated, under various classes, as follows, viz.

Acute, or such as are raised a major comma, and are marked (c).

Close. See that article.

Commensurably. Ditto. Composed, according to Euler, are greater than VIII. Compound. See that article.

Consonant. See that article.

Concordant. See our article Concord.

Defective. See that article.

Discordant. See our article Discord.

Double. Besides those intervals, which are a multiple of some other, by 2, and properly called double: some practical musicians, as Holden, Calkott, &c. on some occasions denominate those intervals double which have a major eighth added to them, and fall between VIII. and XV. Euler calls these Composed Intervals.

Excessive. See that article.

Extreme. See that article.

Flattened. See our article Flat.

Grave. See that article.
conceiving the town to be too close to his magnificent castle, removed it soon after that period to its present site. This change his Grace was the more easily enabled to accomplish, from the circumstance of his being almost sole proprietor, there being only a single feu in the place. And the inhabitants had rather cause to be pleased than sorry at its removal, as both the new houses and situation are greatly preferable to the old. Inverary now stands on a small peninsula, about a quarter of a mile south from the castle, and from its former position. The town, though small, is neat and handsome, particularly its north-eastern front, which produces a very pleasing and picturesque effect when it opens on the traveller approaching it by the great road from the south. Indeed the view of the place, to a stranger visiting by this route the capital of Argythelia, is altogether magnificent. On turning the point of Stronshir, a point of land above two miles distant projecting into Lochline, the far-famed castle, the sprightly town, with its numerous flotilla of boats, the endless variety of peaks and banks, of hill and dale, of wood and water, which, all at once, and as if it were by enchantment, burst upon the eye of the traveller, rivet him to the spot, and overwhelm him with admiration and astonishment. From the vast number of objects which, on turning this point, present themselves to the sight of the delighted beholder, objects not only individually interesting or magnificent, but grouping in the happiest manner, it is probable, that there is not another spot in the empire which can afford a prospect so striking and diversified. But the limits of an article of this kind will not allow us to enlarge on the varied beauties of Inverary. The truth is, that no description, however ably or eloquently written, can give an adequate idea of the fine views to be seen at this place; and we would recommend it to every person who is fond of the lovely and sublime in nature, to gratify his curiosity and taste by visiting Inverary; and employing, at least, a couple of days in examining its interesting and extensive scenery.

The population of the town of Inverary is small, amounting, within the royalty, according to the census taken in 1810, to only 133 souls. There is little doubt that both the place and the population would have been greatly larger, had not the policy, whether judicious or rather questionable, of the family of Argyll, been always aversive to the increase.

There is only a single feu in the place, which was granted in lieu of a similar right possessed in the old town. A great part of the houses was built at the expense of his Grace, and are let to the inhabitants; and such as were erected at the cost of private individuals, have been built on long leases.

Of Inverary little is known previous to its having been made a burgh in the year 1648. There is reason to suppose that, before that period, it was a mere fishing village. But the patronage of the family of Argyll, the erection of the place into a royal burgh, and its becoming the seat of the circuit and sheriff courts, soon raised it to some importance. The town is governed by a provost, two bailies, a dean of guild, and a council of twelve burgesses, and it joins with Ayr, Irvine, Rothesay, and Campbeltown, in sending a member to Parliament. The revenues of the place are but trifling, though the charter vests the corporation with the right of levying harbour dues from every vessel which enters any creek or harbour in the shire. Unfortunately, however, the rights of the burgh were, till within the last few years, hidden in the mysticism of law
Inverary.

Latin; and there is reason to fear that this important privilege, from its having been allowed to remain so long in desuetude, may now be lost. As might be expected, from the circumstances of Inverary being the seat of the courts of law, a considerable proportion of the genteel inhabitants follow this profession. Here, as in other places, it is found to be a thriving profession; and many instances have occurred, within the last 50 years, of men rising from the desk to the possession of considerable landed properties. The English language is generally spoken in the town. The better classes of the inhabitants, of both sexes, speak it with considerable propriety; and are, in general, distinguished for their politeness and intelligence.

There are at present (1817) no manufactories in the town or parish, though the dukedom of Argyll, with that laudable attention to the interest and improvement of the country, which has uniformly distinguished that noble family, have made many attempts to establish them. The great staple, on which the bulk of the population of the place and of the whole coast of Loch-fyne depend for employment and subsistence, is the herring fishery. From the excellence and occasional abundance of the herrings caught in this loch, this is found to be a very lucrative trade, yielding sometimes more than £10,000 per annum. Inverary has no foreign trade; its chief traffic consists in the export of wool and salted herrings to the Clyde and to Liverpool, and in the import of coals, meal, and merchandise, for the use of the inhabitants of the place and neighbourhood.

There are no antiquities or buildings of any interest in Inverary. On the lawn, a little to the south of the castle, there stands a single Druidical stone, as it is sometimes termed, a kind of rude obelisk. Whether it was raised to mark the grave of a warrior, or for some other purpose, it is now impossible to ascertain. Many stones of this description are to be seen in the county of Argyll, and some of them of so stupendous a height and size, that it is quite inexplicable how the old Celts, who are represented as barbarians by certain refined antiquaries and historians, could have contrived to place them in their present position. Indeed, verses as the present generation is in mechanics, it would probably at this day be found an arduous task, either to remove or to erect these singular monuments. In the middle of the town there is a neat monument, raised about the year 1735, to some gentlemen of the clan Campbell, who, towards the close of the seventeenth century, fell victims to their attachment to Presbyterianism. About 14 years ago, a new church was built, compre-

hending under one roof two places of worship. One is used for the Gaelic or parish part of the population, the other for the burgh or English. There are two clergy-
men, who preach alternately to each congregation. Two years ago the building of a new county jail was commenced. The plan of the structure seems to have been designed with a view to the ornament of the place, and the comfort of the unfortunate prisoners. Its site is on the beach, in a very airy situation; and, besides the mere jail, it is meant to contain within its wall a range of handsome court and county rooms. The castle, which stands, as it was already noticed, about a quarter of a mile from the town, is a noble building. It was built by Archibald, Duke of Argyll, immediately after the year 1745; and, though it has been the subject of much criticism to men pretending to superior architectural discernment, yet most travellers of taste always view it with decided approba-

tion. Indeed, the more one contemplates and considers the surrounding scenery, the more will he feel inclined to admire the taste of that distinguished nobleman, under whose auspices Inverary castle was designed and executed: and with regard to internal elegance, comfort, and convenience, it is certain that this fine edifice is not inferior to any nobleman’s residence in the kingdom.

The parish of Inverary extends for nearly 12 miles, along the western shore of Lochfine. Its breadth generally is about 6 miles. The Duke of Argyll is sole proprietor. The population of the parish, without the royalty, according to the census of 1810, amounts to 977 souls. The aspect of the parish is hilly, and much of its soil is bare, and difficult of improvement. Indeed, few of the tenants make the attempt. The traveller is surprised to see the system of run-rig, with all its wretched accompaniments, within a few miles of Inverary Castle. Unfortunately, many of the farms of the parish are subdivided among a number of small tenants, possessing little skill, enterprise, or capital; and notwithstanding the excellent example held out by the late Duke, no improvement could be expected under such a system. The very quantity of valuable wood, which is annually given by the noble proprietor to this swarm of tenantry, and which they consume in renewing or repairing their ill built and ill-thatched houses, would, if accurately calculated, appear incredible, and shew, beyond dispute, the propriety of lessening their number. There was a period, indeed, when the house of Argyll found it politic, like other noble houses, to maintain on their estates a numerous population; when their credit, and perhaps security, depended not a little on the number of men they could bring into the field. But happily those times are gone by; and there can be no question, that the interest of the proprietor, and of the community at large, would be highly benefitted by a change of system. Nay, the change would be advantageous to those small tenants themselves; for not a shadow of doubt can be entertained, that if his Grace were to give them cottages with small tenements of land, or crofts, as they are commonly termed in Scotland, on the side of Lochfine, where they might have access to the rich treasures of its fishery, instead of becoming in their old age, as is now so frequently the case, pensioners on his charity, their condition would be comparatively raised to a state of independence and of comfort.

The woods of Inverary, both natural and planted, have been long known and admired for their beauty and extent. There are great quantities of fine old oaks, sycamores, ashes, limes, chestnuts, &c. and the magnificent beeches can scarcely be matched in the kingdom. The Woods of this parish have been reckoned worth nearly half a million of money; and though the data on which the calculations were formed may not be perfectly satisfactory, there can be no doubt that, from their extent, as well as quality, they must be of prodigious value. Inverary is situated in North Lat. 56° 28', and in West Long. 5°. (w. 12.)

INVERKEITHING is a royal burgh, and sea-port town of Scotland, in the county of Fife. It stands upon a rising ground on a bay of the same name, on the north side of the Firth of Forth. The town consists principally of one street, through which the great north road passes, and of some bye lanes. Some of the houses are good, but many of them are very old, with staircases on the outside. The town-house, which was built in
1770, contains a prison, and apartments for the business of the burgh, and for public meetings. The parish church, and the church for the burgher seceders, are the only other public buildings.

Inverkeithing is governed by a provost, two bailies, a dean of guild, and treasurer, who are elected annually by the councillors and the deacons of the trades. It received its charter from William the Lion. David I. resided in it; and within these 50 years the vestiges of his house remained. King James VI. ratified the charter granted by preceding monarchs, by a writ dated 4th May 1593.

There are almost no manufactures in Inverkeithing. An iron foundry, on a small scale, has been established; and there are several salt pans, which annually make about 15,000 bushels of salt. The trade of the town consists principally of the export of coals, to the extent of about 25,000 tons annually. The harbour has from 15 to 15 feet of water at spring tides, and there are good quays for loading and unloading vessels. The bay of Inverkeithing, which is separated from the Firth of Forth by the Ferry hills, affords excellent anchorage for vessels of any burden; and it is here that the ships of war stationed in Leith Roads often ride in severe storms. The Dominicans and the Franciscans had convents here, but no remains of them are now to be seen. The population of the town is about 1800. In the year 1811, the population of the burgh and parish was

INVERNESS, an ancient and flourishing burgh and seaport town of Scotland, and capital of the county, takes its name from its situation at the junction of the river Ness with the Moray Firth. It is 106 miles north-north-west of Edinburgh; its lat. is 57° 30' 5" North, and its Long. 4° 5' West. Being, from its geographical position and importance, resorted to from all parts of the northern counties for many necessary articles of consumption, as well as in consequence of its circuit courts, and of its seminaries for education, and meetings for business and conviviality, it is considered as the capital of the Highlands. The older and larger portion of the town occupies an extensive alluvial plain on the eastern bank of the river, stretching towards the sea, from the more elevated country rising abruptly over it; whilst the more modern part, lies in the same plain on the western bank. Its noble and majestic river, ever filling its banks with a smooth and unvarying stream, the richness of the gardens, nurseries, cultivated fields, and hedge rows in its neighbourhood, the rocky, broken, and beautifully wooded hills rising from the plain to the west, its vicinity to the Moray and Beauty firths with their bold shores, combine to render its situation one of the most delightful that can be imagined. Although the town itself lies low, it is nevertheless healthy; and it has the advantage of possessing some very beautiful and elevated walks in its vicinity, where a pure and salubrious air, as well as the most splendid and exhilarating views, may be enjoyed. Amongst these, the ascent to the summit of Craig Phadrack (see Forts Vitrified) may be particularized, whence may be commanded, a prospect as varied and extensive as the eye can covet. The eastern part of the town contains one large and spacious street, called East-street, running from east to west along the foot of a steep bank. From this, two others called New-street and Church-street, branch off at right angles in a northerly direction; and there are besides these, one or two running with a considerable ascent up the bank to the south. In this part of the town are many buildings of considerable antiquity, in which are observed many curiously carved stones with grotesque figures, coats of arms, and inscriptions. East-street is connected with the western part of the town, through Bridge-street, by a very picturesque, though rather inconvenient old bridge of seven arches, built by subscription in 1686. Beneath the arches are projecting ribs of stone, producing a very massive effect. A troublesome toll of a halfpenny is levied from people passing this bridge on foot, which ought certainly to be done away. The western part of the town is less ancient and less extensive, but there are a good many respectable looking houses facing the river, and some neat streets have been lately begun. A little above the harbour, the two sides of the river are also united by a very handsome wooden bridge, of modern erection, much admired for the ingenuity and excellence of its structure. A very beautiful walk has been lately made on the eastern bank, running between the ends of the two bridges, forming a delightful promenade. The town contains two churches and a chapel of ease; the former have three established clergymen, and the latter one. In one of the churches Gaelic is exclusively preached, and in the chapel of ease it is employed alternately with English. There is also an Episcopal chapel, with a bishop, and a methodist chapel. The tolbooth and court-house, situated at the entrance to Church-street from East-street, is a very handsome building, having an extremely elegant tower and spire rising over the front. This is 150 feet high, of very beautiful proportion, and was built about 20 years ago by the architect of the spire of St. Andrew's church in Edinburgh, to which, though not so taper, it bears considerable resemblance. In the ground floor of the building there is a military guard-house. The courtroom, though by no means bad in itself, is rather inconvenient in its entrance; and the interior arrangement would admit of considerable improvement. Here, during circuits, are held the criminal and jury courts, for the counties of Orkney, Caithness, Sutherland, Ross, Cromarty, Inverness, Nairn, and Moray. The cells for criminals, on the second floor, are furnished with cast iron bedsteads, benches, &c., on the plan of the benevolent Howard. There is also a long gallery in front, with large open barred windows, where the prisoners are allowed to take air and exercise. The third floor is occupied by the debtors' rooms, and apartments for those confined in civil cases. The townhall is a large plain building, opposite the head of Church-street, having in front a pavement of 80 or 90 feet square, serving as an exchange. The ground-floor consists of shops; in the second floor is the council-chamber, and a charter-room; and the upper is employed for the meetings and courts of the dean of guild and his council. Near the upper end of Church-street are the assembly-rooms of the Northern Meeting, erected by subscription about 1789. The edifice is rather heavy in its exterior, but contains large and elegant sitting and ball-rooms, and several commodious smaller apartments. It is intended for the accommodation of the nobility and gentry of the northern counties, who meet annually for a week in the month of October for the enjoyment of field sports; the evening of each day being spent in a public dinner and ball. The building was originally
The remains of the ancient castle of Inverness, though originally of importance, are now very trifling. They are situated on the western part of a green hill, rising over the river a little above the bridge. On the site of these ruins once stood the castle, in which King Duncan is supposed to have been murdered by Macbeth. The fortress of the usurper stood on the eastern extremity of the hill; it was razed by Malcolm Canmore in detestation of his father’s murderer, and the more modern castle was afterwards erected by him. This was occupied in 1715 by the officers of the royal army, having been repaired, and barracks and a rampart added to it; but it was destroyed in 1745 by the rebels. At the junction of the river with the sea, stands the remains of a fort erected by Cromwell, on the site, and partly with the materials, of an old monastery of Dominicans, or Black Friars, founded in the 13th century by Alexander II. The fort was a regular pentagon, with bastions, ramparts, and wet ditches, a covered way and glacis. The whole incloses four acres of ground, and might have held 2000 men, and 400 horses. It was nearly demolished by Charles II. in 1682, and has since fallen completely to decay, nothing now remaining of the vestiges of the ramparts. The garden of the Dominican monastery is now the glebe of one of the ministers, and the site of the church is a small burial place. The principal burying place of the town and parish is the chapel yard, an inclosure of about six acres, on the east side of Church-street.

In the sixth century, Inverness was the capital of the Pictish kingdom; when St. Columba left Icolmkill, and came to the Pictish court, ad ostium Nessae, in order to convert Brudeus II. to Christianity. The first burgh charter was granted to the town by Malcolm Canmore, (then residing here,) in the year 1067. It afterwards had charters from King William the Lion, in 1175, and from Alexander, David, James I. and Queen Mary. The last charter it received was from King James VI. in 1591, ratifying all former grants, and, amongst other immunities, appointing a market twice a week, with eight free fairs yearly. In 1310, Inverness was taken by Robert Bruce. In 1645, Montrose defeated Colonel Urrey near the town. In 1649, Colonels Middleton and Monro seized it for Charles II., but were soon driven away by the Parliament General; and, in 1745, it was occupied by the army of the Pretender, previous to the battle of Culloden. Inverness, in conjunction with Fortrose, Nairn, and Forres, sends a member to parliament, each in rotation being the returning burgh, and having a casting vote.

The population of Inverness has been gradually increasing for a considerable time, but it seems to have grown in a much greater ratio of late years. This arises from a variety of causes, of which the works of the Caledonian canal, and the consequent accumulation of labourers, may be offered as one of the most obvious and important. In 1791, it contained 5107 inhabitants; in 1801 the number rose to 8742; and, in the return of 1811, the total amounted to 11353. The Gaelic language is of course much used amongst the lower orders; but English is spoken by all ranks with a degree of grammatical precision, hardly to be met with in any other part of Scotland; and although it is accompanied by a particular provincial accent, by no means pleasant, yet the pronunciation is generally much more correct here than it is elsewhere. Some attribute this to the circumstance of the intercourse of the inhabitants with Cromwell’s soldiers, having influenced the language of their descendants; but it is perhaps better explained by remarking, that Gaelic having been the common me-
Inverness.

The town is governed by a provost and four bailies. The provost is assisted by a council, consisting of 21 members, who have a clerk, and a clerk-depute. The new council is annually elected at Michaelmas by the old council, and afterwards elects from its body the new provost and bailies, and the dean of guild and treasurer. The provost, however, is usually continued in office for three, and the other magistrates for two years. There are six incorporated trades, who annually elect at Michaelmas six deacons, and six box-masters or treasurers, each corporation having its own peculiar deacon and box-master. The six deacons elect a deacon-convenor, who presides over, and attends to, the interests of all the corporations; they elect at the same time a general box-master. The six corporations are represented in the council by their deacon-convenor, (who by virtue of his office is a member,) and by two deacons annually elected by the town-council. There are, besides these, several other crafts not incorporated. The dean of guild holds a court for determining all matters relating to the guildry, and particularly for preserving and upholding its fund, which is in a very thriving state.

The common funds of the town are respectable, and considerably on the increase. Its income is devoted to public purposes, and to giving annuities to decayed persons, and salaries to the different teachers of the town. The accounts of the burgh are made up yearly, and are left in the council chamber for several weeks, for the inspection of all concerned. To aid the magistrates in managing the police of the town, about 70 or 80 of the most respectable tradesmen are annually nominated as constables. The streets are cleaned regularly every morning, and the manure so collected is sold to the neighbouring farmers, at the rate of about half-a-guinea for a double cart-load, producing several hundred pounds a-year. The lamps are lighted by contract, and are in number about 150.

There are several societies in town, such as the Inverness Highland Society, with president, vice-president, directors, and members; the Northern Horticultural Society, with a patron, vice-presidents, and councilors; a saving-bank for the poor, with directors; a Farming Society, with president and vice-presidents; an Athenaeum, where periodical papers of all kinds are taken in, with a president and committee of management; a society for suppressing begging, with a president and committee, 1st, for paying the allowances to, and investigating the circumstances of the poor; 2d, for furnishing the paupers with employment; 3d, for superintending the instruction of children; and, 4th, a medical committee. There is also an Inverness Auxiliary Bible Society, with a president and committee; and, what does infinite honour to this town, an Auxiliary Deaf and Dumb Society has been just established. A respectable medical society has been also instituted. Besides these, there are several mason lodges in town.

The trade and manufactures of Inverness have improved with its increasing population. Its harbour is safe and commodious, admitting vessels of 200 tons to unload at the quay; and vessels of 500 tons may ride in safety in the Moray Firth, within a mile of the town. The tide flows up to the bridge; small vessels are occasionally built here. The exports are considerable, and consist of grain, (chiefly wheat,) wool, skins and hides, hemp, flax, and woollen manufactured goods, wood and building stone. The imports, however, are to a still greater extent, consisting of London dry goods, and groceries, coals, lime, barley, and hemp and flax for manufacturing. In this trade there are a number of vessels employed, of which those registered as belonging to this port, are 51, forming an aggregate of 2746 tons, and employing 201 hands. The trade with London is the most frequent, a circumstance tending to keep Inverness and its neighborhood always in an advanced state of acquaintance with the elegance and luxuries of life. The carrying trade to and from the metropolis, is conducted with the utmost regularity. The vessels belonging to the London Shipping Company, are about 120 tons burden, and are six in number; they are built as much with a view to the accommodation of passengers, as for the conveyance of goods. The Leith Shipping Company have three smacks, and the Aberdeen Shipping Company have the same number. The royal mail starts every day to run by Aberdeen, and the Caledonian diligence sets off twice a-week by the Highland road, furnishing conveyances by land to Edinburgh and London. Besides these there are numerous carriers and bye-posts. The bank of Scotland, the British Linen banking company, and the Perth bank have each of them a branch here. There are also agents established in Inverness for six different insurance companies.

Though provisions are plentiful, Inverness cannot be called a very cheap place. The butcher market is well supplied. There are also plenty of sea-fish and salmon; which last are exported in great quantities to London. Vegetables and the more common fruits are in abundance.

It is not very easy to predict what probable increase of trade may be expected to accrue to Inverness from the opening of the Caledonian canal, (for which see Navigation, Inland.) That it will have some influence in promoting the growing importance of the town, cannot be doubted, though we fear that the operation of this cause, may have been rather overrated by the eagerness of public anticipation. The discovery of the steam-boat, however, by offering a new and more certain mode of towing vessels through the lakes, must certainly obviate much of the difficulty of their navigation, the apprehension of which would have naturally operated to diminish the passage through them. We may therefore be allowed to hope that Inverness may one day rise to a considerable degree of magnificence.

If this great work shall have any effect on the trade, manufacturers may also reasonably expect that it will give energy to the manufactures of Inverness. Surrounded by a populous country, and possessing a command of water, it is well situated for manufactures of various kinds; but as yet comparatively little has been done in this way. The principal manufacture is that of hempen cloth, sent in considerable quantities to the West Indies and America, for packing cotton and coffee. Much of this stuff is prepared for home consumption, being used as sail cloth, and for corn and coal sacks. There are three establishments of this kind, employing a number of hands. There are two woollen manufactories here, one of them chiefly employed in making tartan cloths for the Highland markets. The other has produced very excellent superfine cloth, but this part of the manufacture has been relinquished for the more profitable one of country cloths, and negro clothing for the West India market. An iron foundry was esta-
INVERNESS-SHIRE, the name of the largest of the counties of Scotland.

The county of Inverness is about 94 miles in length from east to west, and about 50 miles at its greatest breadth. It is bounded on the north by Ross-shire, and the Moray Firth; on the east by Nairn, Moray, Banff, and Aberdeen-shires; on the south by Argyle and Perth-shires; and on the west by the Atlantic Ocean. Besides this, which may be termed the continental part of it, a number of the Hebridean islands belong politically to the county. In considering the surface of this extensive and important part of Great Britain, it will be convenient to begin with a description of the grand outlines of its geography.

The great Caledonian Glen, or, as it is denominated in Gaelic, GLEN-MOR-NA-ALBIN, is the most remarkable feature in Inverness-shire. Running in a straight line nearly from north-east to south-west, it divides the county into two almost equal parts. It may perhaps average somewhat less than a mile broad in the bottom, but towards its summit level, it is in many places scarcely a quarter of that width. The sides of the hills rise so very abruptly on both hands, and the shapes of their steep fronts seem so much adapted to one another, that the least observing person can hardly travel along its length, without the idea occurring that it must have been produced by some vast and sudden convulsion.

The northern extremity of this extraordinary glen, opens by the river Ness into the Moray Firth, and following it south-westwards from this point, we find it occupied by Lochs Ness, Oich, and Lochy, whence it extends into the Western Ocean by that long inlet of the sea called Loch Linhe. In examining the straths and glens tributary to this great one, we find that they are eight in all; of which number, (speaking in a general manner,) four join it from the west north-west, viz. Glen Urquhart, Glen Morriston, Glen Garry, and the glen or strath of Loch Arkaig. The remainder come into it from the east south-east, and are Stratherrick, Glen Ghouy, Glen Spean, and Glen Nevis; the three last situated in the district of Lochaber. Turning to the west coast of the county, we find it broken by six arms or bays of the sea, besides that of Loch Shiel, there forming its southern boundary. These are Loch Moidart, Loch Aylort, Loch-ananougal, Loch-na-gaul, Loch Nevish, and Loch Hourn. The fresh water lake Loch Morrer, and several small glens, discharging independent streams into the Western Sea, tend still farther to disturb the continuity of the mountains in this part of the county. In the northern quarter of the shire, we notice the great glen of Strath Glass with its tributaries, running nearly north-east, and opening into the firth of Beauly. To the south of the town of Inverness, portions of Strath Nairn and Stradearn, or the strath of the Findhorn, run through the county in a direction opposite to the bevelment. Three gentlemen, who at the time of the earthquake happened to be approaching Inverness from the west, when at a considerable distance from the town, distinctly heard the large bell toll twice, a circumstance entirely unnoticed amidst the bustle, by those who were in the streets or houses of the place. It appears to have been admitted by many gentlemen of Inverness, who had resided long in the West Indies, where such convulsions are frequent, that they had never felt a smarter shock.

From January till the present period, October 1817, there have been no less than five other shocks at Inverness; one of which was very violent, and generally felt over the central and western parts of Scotland. (T. L. D.)
nearly north north-east. And farther south still, on the
great strath of the river Spey, we find the district of
Badenoch; whence Inverness-shire is projected in a
north-east direction between the shires of Banff and
Moray, a considerable district round Castle Grant, be-
ing by them insulated from the rest; and in this way
it includes a large portion of Strathspey.
Mountains.
All these glens are, comparatively speaking, narrow,
and are bounded and divided from one another by very
high mountains, which consequently form a great
portion of the surface of the country. It is therefore
necessary in this place, to notice one or two of the most
distinguished. Maffrouvoumie rises over the north side
of Loch Ness, between Glen Urquhart and Glen Mor-
rison; and is very conspicuous from its round-headed
top. Its height above the level of the sea is 3060 feet,
and it is visible from the east at a great distance. Cairn-
gorun, and Brae Riach, are two mountains rising over
the district of Ruthiemurchus, on the Spey. By the
barometrical measurement of Dr. Skene Keith, the for-
er is 4214, and the latter 4304 feet above the level
of the sea. But in Inverness-shire, as throughout the
rest of the island, the highest ridge approaches much
nearer to the Western than to the Eastern Sea. Ac-
cordingly we find, that the great mountain masses are
accumulated towards the former side of the county, and
it is there that Glen Ness is situated. This gigantic
mountain is 4270 feet; but it is not more remarkable
for its superior altitude, than it is for the circumstance
of its having its base almost washed by the sea, whence
it towers up at once with a grandeur no where to be
equalled in these kingdoms. It is never to be found
without snow, and its top is almost constantly envel-
opied in clouds; but when it is uncovered, the view com-
manded from the summit is the most extensive that can
be imagined, taking in a range of more than 170 miles,
and embracing the greater number of the Hebridies.
By going about a quarter of a mile up the river, above
the house of Glen Nevis, it is easily ascended by one
of its western ridges.
Lakes.
The most important lakes of Inverness-shire are,
Lochs Ness, Oich, Lochy, Arckeg, and Morror, already
mentioned; Loch Clunie in Glen Morrison; Lochs
Garry and Quoich in the district of Glen Garry; Lochs
Laggan and Treig, emptying themselves into Glen
Spear; and Loch Maddy, running into Strath Glass.
These Loch Ericht may be added, being partly in this
county, and partly in Perthshire. These lakes, de-
pending for their shapes upon the lengthened glens
in which they are situated, are all long and narrow.
They generally deepen suddenly from within a few
yards of the margin, where they are surrounded by a
shallow beach. They are of various magnitudes, being
on an average from six, to twelve, and fourteen miles
in length.
Loch Ness.
Of all these Loch Ness is the largest, being twenty-
two miles in length, and from one to two miles broad.
Its common soundings are from 116 to 190 fathoms,
and its extreme depth is 135 fathoms. In exemplifica-
tion of the remark made above, as applying generally
to all the lakes in Inverness-shire, we may mention,
that Loch Ness is from 15 to 20 fathoms deep close to
the narrow shelf, extending a little way into the lake.
It is unquestionably from the circumstance of its great
depth, affording a rapid and continual succession of
warmer strata of water, to occupy the place of those,
which, being cooled at the surface, have consequent-
ly sunk from, their increased specific gravity, that the
lake is never known to freeze; though a portion of
the water, when removed from it, freezes as fast as
that of any other. We do not conceive the theory, as-
scribing the cause of this phenomenon to the existence
of a subterranean fire, of much value. The lake and
river are no doubt observed to smoke in severe frost;
but this very naturally happens from the cause al-
ready stated, as operating to prevent its congelation;
for owing to the constant supply from below to the
surface, of water of a higher temperature than the air,
evaporation will more readily take place, and will
be more in the more apparent to the eye the greater
the cold. The river, being supplied from the stratum of
water last arrived at the surface of the lake, which is
consequently the warmest, its course being short, not
more than five or six miles; its stream being steady
and forcible, and (from the great quantity of water it
has to dischage,) being more hurried than its actual
fall would otherwise render it, has not sufficient time
to be cooled down to the freezing point, and, therefore,
like the lake itself, it remains unconsgealed. In Novem-
ber 1812, the thermometer being at 2° Fahrenheit,
Loch Ness remained perfectly free from ice; but on the
shallower lake of Dochfour, into which the river
Ness runs, about a quarter of a mile from the large loch,
there was a thin coat of ice, of considerable extent. On
the 15th of November 1755, being the day of the dread-
ful earthquake at Lisbon, the water of Loch Ness rose
suddenly without any apparent cause, and rushing
south-westwards with violence, continued to ebb and
flow with great agitation for more than an hour.
During the earthquake on the 15th of August 1816, (re-
ferred to in our article INVERNESS,) the people on board
the dredging barge, moored at the foot of Loch Ness,
although sensible of no motion in the water, were awak-
ened, and much alarmed by the rombo, thinking that the
vessel had broke from her mooring chains.
The water of Loch Ness, as well as that of the river
of the same name, produces very obstinate diarrhoea
in strangers who drink of it; and horses are affected by
it in a similar way. This property was long supposed
to arise from its containing a certain minute portion of
sulphur; but we can venture to contradict this, on
the authority of Dr. Nicol of Inverness, who has kindly
communicated to us the result of some of his expe-
riments. That gentleman did not observe the slightest
indication of sulphur, though faint traces of the exist-
ence of muriatic acid seemed to manifest themselves.
He is disposed to attribute the laxative effect to a great
portion of putrid vegetable matter, mechanically ming-
gled with the water of the lake; and we conceive this
to be by far the most rational mode of accounting for
it. We hope, however, that this ingenious gentleman
may be induced to prosecute an inquiry, which cannot
fail to be highly useful as well as interesting.
Besides those we have enumerated, there are a multi-
tude of smaller lakes, each of which in any other part
of Britain would rise into importance.
The greater rivers of Inverness-shire are, the Ness,
the Lochy, the Beauty, and the Spey; the lesser are,
the Findhorn, the Nairn, and the Nevis. These have
numerous large streams supplying them; as the Enne-
ic and the Coalie, the Murrison, the Garry, the Fea-
loin and Fuyers, and the Farragig, all tributary to the
Ness; the water from Loch Arckeg, and the Roy and
Spear united, falling into the Lochy; the Farrer, Ca-
nuich, and Glass, forming the Beauty; and the Truim,
The Trommie, and the Feshie, running into the Spey.
Almost all these rivers are clear, rapid, and rocky. Those discharging themselves into the East Sea, have much longer courses than those entering the Western Ocean.

From the innumerable huge trunks and stocks of trees found every where in the extensive mosses of Inverness-shire, there can be doubt that at one period the whole country was covered with forests. In many places, the roots and stumps, in the growing position, and as if the stems had been newly removed from them, are so amazingly numerous, that there is often not more than two feet of distance between them. In other mosses, as in one cut through by Mr. Macpherson Grant's canal in Badenoch, three courses of roots were discovered, which had grown one above the other. Judging from the greater number of specimens dug up all over the county, the Scotch fir was unquestionably the most abundant tree; but the birch, the hazel, the oak, the mountain ash, and the alder, must have been also very numerous. The remains of all these trees, but particularly of the fir, are found on very highly elevated situations, far above the point where it would now be possible to raise trees of any kind by human exertions. The carbonized crust which generally appears on the stocks and stems of the trees, would seem to indicate that the forests had been destroyed by fire; and the trunks found lying horizontally, are often hollowed out above, something in the form of a spout for conveying water, as if their upper sides had continued to burn after they had been extinguished below, by falling into moist ground. Many of these trunks are enormous. Some very large masses of oak were brought up by the dredging machine employed in deepening the line of the Caledonian Canal, in Loch Dochfour, from under 16 feet of gravel, at the bottom of the lake. One of these fragments measures 30 feet round; and though only a small portion of the original tree, it contains about 220 cubic feet. It is black as ebony, and perfectly fresh and hard. At the upper end of Loch Garry, there are the wrecks of a magnificent oak forest, not, as is commonly the case, embedded in peat earth, but lying on the surface of the solid ground, like trees newly thrown down. A great many years must have elapsed since those trees were laid prostrate, yet the remains now are very old and beautiful birch wood growing on the ground they formerly occupied. We measured one of these trunks, and found it to be 23 feet long without a branch, 16 feet round at the root, and 11 feet in circumference at the small end, under the fork. With the exception of an inch or two of the exterior, it appeared perfectly fresh. It lies within a yard of the stock whereon it grew; but it is not easy to tell, from appearances, how it was preserved from it. The stock is worn away, and hollowed out, so that it now encircles a large birch tree of more than a foot diameter, self-sown, and growing vigorously within it. The birch wood seems to have completely usurped the place of the ancient oak forest; for there are no trees of the latter species in the neighbourhood, excepting a few stunted bushes thinly scattered here and there.

The oak is now rather a scarce tree in Inverness-shire, although it is found in profusion as copse wood. The banks of Loch Ness, and those of many of the other lakes, are covered with it, as well as with ash, mountain ash, aspen, holly, and almost every variety of tree. Natural birch woods are very numerous, as on Loch Ness, in the vales of Urquhart and Glen Mor-riston, on the banks of the Beauty and of Loch Lag-gan, at Rothiemurchus, Kinrara, &c. Perhaps the finest any where to be met with, are those on the banks of the Feshie at Invereshie, and those about Loch Garry, where there are several thousand acres of this beautiful tree in the highest perfection. The natural fir woods are immense, both as to number and extent. Those of Rothiemurchus are estimated at fourteen or sixteen square miles. On the sides of Loch Arkaig, in Glen Garr, Glen Morriston, Strath Glas, Glen Strathtan-far, and at the head of Loch Shiel, the fir forests are so enormous as to go beyond calculation.

There are few counties in Great Britain possessing scenery, a greater profusion of grand and splendid scenery than that of which we are now treating. To give even a faint idea of its various natural beauties, would greatly exceed our limits. It is, however, impossible to pass over this part of our subject, without directing the attention of the lover of nature to those spots where he would most delight to wander. The whole line of the Caledonian Valley, with its lakes, and its romantic tributary streams and glens, furnishes one continued series of enchanting scenes. The Fall of Foyers we have already noticed, (see that article.) In Urquhart, Glen Morriston, and Glen Garry, there are also very fine falls, attended by the most magnificent accompaniments of rocks and woods. The scenery of Loch Garry and the river issuing from it, is perhaps almost unrivalled anywhere. In Glen Nevis there are two very grand water-falls, and, particularly one of them, of much greater height and magnitude than the Fall of Foyers, yet little if at all known by any body but the inhabitants of the valley. The salt-water lake called Loch Leven, expanding above Ballachulish ferry, at the southern point of the county, possesses a combination of every thing that is beautiful or sublime in landscape. There the bold shores, now prominent and now retiring, covered with groves of the freshest and most vigorous natural trees of every description, almost dipping the extremity of their branches in the sea—the scattered cottages and clustered fishing villages—the boats—the islands—and, above all, the majestic and fantastically formed mountains, rising in mist around it, having in many places rocky and shelved fronts—all conspire to render this lake one of the most lovely and interesting in nature. Part of the scenery on the river Beauty, called "The Dream," is so exquisitely beautiful, as almost to induce the supposition, that the name may have originated in its resemblance to those ideal pictures offered to the sleeping fancy. The banks of the Spey, from Aviemore upwards to the west end of Loch Inch, comprising the scenery of Rothiemurchus and its lakes, Kinrara, Invereshie, and Belleville, are well known. But there are spots amongst the deep glens of the Cairngorm mountain, but rarely visited, where the artist might study nature in her wildest garb.

In Inverness-shire, as in all other mountainous countries, springs of water of the greatest purity are found everywhere. Those impregnated with mineral substances are more rare, or, at least, are as yet little known. Water of sulphureous impregnation issues in various places from the hills of Loch Ness; and chalybeate springs are found in various situations, particularly in the district of Strathspey.

In a county so varied, and so extensive as Inverness-shire, it is natural to expect a great variety of climate. From the constant alternation of hill and valley, the circumstance of two thermometers within half a mile.
of each other, denoting several degrees of difference of temperature, is not uncommon. The eastern part of the county, like the rest of the coast of Scotland, on the same side of the island, is subject to cutting east winds, often accompanied by dense and chilling fogs. But the prevailing breeze, as indicated by the general inclination of single trees in exposed situations, is unquestionably that blowing from the south-east. It is owing to the prevalence of this, that there is such a marked difference between the climate of the east, and that of the west coast, in respect to moisture, the former being comparatively dry, whilst the latter is exposed to constant and heavy rains. The watery vapour swept up by the wind, in its progress over the vast expanse of the Atlantic, is attracted by the summits of the great mountain chain, running along the western side of the island. It is there condensed, and thrown down on the narrow stripe of country at their base, in heavy rains, continuing with a duration, corresponding to that of the current supplying them. But it is only when this wind blows with long and uninterrupted violence, that any great proportion of the aqueous accumulation thus formed is wafted over to the eastern side; and when this does happen, the extent of country between the hills and the sea, being infinitely greater there, the rains are more diffused, less violent, and less continued. But as the rain falling on the east coast, comes more frequently from the sea in its own immediate vicinity, it is generally remarked, that when it occurs, it almost always furnishes a security of the weather being fine on the west coast. Upon the whole, snow lies for a shorter period on land of the same height, on the western, than on the eastern coast. Those observations are to be understood as being merely general; particular places being subjected to particular modifying circumstances, rendering them exceptions to these laws.

The soil and surface of Inverness-shire, is very various. It has been calculated, that only about one fourth part of the county is arable land; and that probably twenty-six of the remaining parts are hills in a great measure covered with heath. Deducing these hills and moors then, the rest consists of clay, haugh or holm land, loam, gravelly or sandy soil, and till. Of these different descriptions of soil, the three first are the most rare, and the two last the most frequent. According to the map accompanying the agricultural survey of Inverness-shire, clay appears extending in a very narrow stripe along the shores of the Beauly and Moray firths. Haugh or holm land is found on the banks of the river Ness, in Glen Urquhart, at Invermoriston, at Fort Augustus, Loch Oich, on the river Lochy, and in Glen-gean; on the west coast at Meildart and Glenelg, and some few intervening spots; along the river Spey in Badenoch, where it is most extensive; and on the river Findhorn, near Freeburn, and about the Loch of Moidart, tributary to it. The loam is found at Inverness, stretching to the east of the town, and from the Caledonian Canal, running westward to Beauly, along the edge of the clay just noticed. There is a small patch of it stretching northwards from Boleskine; Glen Roy is all loam, and part of the banks of the river and lake of Treig, the north shore of Loch Hourn, and the coast towards Glenelg, the banks of the river Nairn above and below Cartnay, and the north bank of the Spey from Rothiemurchus to below Grantown, are all of this description of soil. To enumerate the gravelly, sandy, or tilly localities, would lead us beyond the bounds prescribed for this article.

The mineralogy of Inverness-shire is as yet but very imperfectly known, and much interesting matter for the geologist, doubtless remains to be investigated. The rocks are primitive, and micaceous schistus appears to be by far the most universal: the district of Lochaber is almost entirely composed of this rock, having imperfect garnets disseminated through it. In Glenmoriston, some beautiful specimens of gneiss, with mica in hexagonal crystals, is to be procured. Granite, and gneiss, are abundant throughout the country; and sienite, hornstone, hornstone slate, claystone, compact feldspar, and hornblende rock, are also to be met with in different situations. The granite is chiefly of a bright red colour, and is porphyritic in its structure. In Badenoch and Strathspey, however, it is found with black, and sometimes with greenish mica in it. Red claystone porphyry is plentiful; particularly on Ben Nevis, where a whole precipice, or rather a side of the mountain, is composed of it. Porphyries of beautiful bluish purple, and of smoke-coloured grounds, are also to be met with. Quartz rock is to be observed in many places; and near the ferry of Ballachulish, there is a particularly fine section of it. Primitive limestone is common everywhere, and is quarried, and burnt for economical purposes. On Ben Nevis, and in other places, there are some richly coloured marbles; but of these, little use has as yet been made. Fine blue slate is quarried near Ballachulish; but the most extensive manufacture of them is on the Argyllshire side of the ferry. Lead ore has been found on Ben Nevis, at Invercauld, and on the side of Loch Arkaig. Graphite, or plumago, appears in a vein, on the mountain dividing Loch Laggan from Glen Gluoy. Silver was discovered in Badenoch, but the mine was not wrought with any success: and iron ore has been noticed, in several parts of the county; but not in sufficient quantity to render it worth working. The topaz is found in the mountains of the Caingorms group; where rock crystals, of all colours, well known by the name of Caingorms, are dug out by the Highlanders, from the drusy cavities of granite. The large fresh water mussel; (mytilus margaritifera) containing pearls, are fished up from some of the rivers.

The flora of this county is very ample, but we shall only notice a few of the rarer plants contained in it. On Ben Nevis are found Veronica alpina; Juncus tri- fusus, Hymenoxys, Poa flexuosa, Saxifraga rivu- tosa, Nelliera ceratoides, Lichen erinaceus, Dicranum fimbriatum, Dicranum foetens, Dicranum purum, Dicra- num hyperboreum, and Bryum interruptum. On the Cairngorms; Corvus nucu, Acer pseudoplatanus, Silene acaulis, Rubus chamaemorus, Phleum alpinum, Alchemilla alpina, Helota nana, Spilochorum tenece, and Grimmin co- nostoma. Rupia maritime, and Pulmonaria maritima, are met with in Glenelg; and Juncus squarrosus at Loch Hourn. Saxifraga trinaetys, and Satyrium repens, grow in the neighbourhood of Inverness.

Wolves, and even bears, were once natives of this county; but they, as well as the wild oxen, have long ceased to exist. Red deer, (Cervus elaphus,) and roe; (Cervus capreorus,) are in abundance everywhere. Foxes, (Canis vulpes,) are very numerous; and the natives suppose there are three varieties of them. Fox-hunters are constantly employed to destroy them, but their numbers seem to be little reduced, and they continue to do a great deal of mischief. Wild cats, (Felis {fur), are numerous, large, and very fierce; there are also badgers, (Ursus mela,) and the different varieties of the weasel tribe, (Mustela); and the lakes-
and rivers abound with others, (Musca lata.) Hares, both common, (Lepus timidus,) and alpine, (Lepus variabilis,) and rabbits, (Lepus cuniculus,) mice, (Mus musculus, Mus sybaicus, Mus agrestis,) rats, (Mus rattus, Mus domesticus,) moles, (Talpa europaea,) and bats, (Vesperillo auratus,) are all plentiful within the abundance of the sea are frequented by seals, gannets, (Phoca largata,) and common, (Phoca vitulina.) Most of the kinds of eagles, and hawks, (Falco,) and owls of different sorts, (Otriz,) are to be found in this county. Ravens, (Corvus corax,) crows, (Corvus corone, frugilegus, cornix, nonnulata,) and magpies, (Corvus picea,) are numerous; and almost all the smaller birds common to the latitude are found here. Of the gallinaceous, Inverness-shire had to boast of possessing that beautiful bird the capercailzie, or cock of the wood, (Tetrao urogallus,) nor is it long since it was finally extirpated, the last having been killed in the fir forest of Strathglass, in the memory of people now alive. As this noble game is plentiful in Norway and Sweden, whence it are sometimes brought to London for the tables of the luxurious, it is to be regretted, that it has not imported alive into the Highlands of Inverness-shire, where, by a little attention, they might again become natives. Black game, (Tetrao tetrix,) grouse, (Tetrao attilagon,) and ptarmigan, (Tetrao lagopus,) are very numerous; also partridges, (Tetrao perdix,) woodcocks, (Scopola rusticola,) and snipes, (Scolopax gallinago, et gallinula,) pheasants, (Phasianus colchicus,) have been introduced at Culloch, and are beginning to spread themselves. Of reptiles, vipers, (Coluber herus,) adders, (Anguis cryz,) and slow or blind worms, (Anguis fragilis,) are to be met with, but are not frequent. The fish of most consequence is the salmon, (Salmo salar,) which runs up all the rivers with any connection with either sea. There are plenty of trout, (Salmo trutta, fario,) of various kinds, in the different lakes and streams; those of Loch Ness are very delicious. The char, (Salmo alpinus,) is found in Loch Ruthven in great perfection, and also in one or two other lakes. Sea fish of all kinds abound on the coasts, so as to produce a plentiful supply of food.

The name of Inverness-shire, is certainly circumspectly derived from the fall of Foyers. We have already stated, (see article Foyens,) that ess, signifying a waterfall, loch an ess is the lake of the waterfall; whence the names of the river, of the town, and lastly of the county. Inverness-shire contains 31 parishes, eleven of which belong to the Hebrides. These parishes are scattered amongst five or six different presbyteries. The districts, into which the county has been divided by public arbitrary usage, are, Lochaber, Moidart, Arisaig, South and North Morler, Knoydart, Glengarry, Gleenelg, Glenmoriston, Urquhart, Strathglass, the Aird, Inverness, Petty, Arderenier, Stratherie, the Braes of Strath Nairn, the Braes of Stralchien, Badenoch, Rothiemurchis, and Strathspey; all of which are separately distinguished from one another. There are four sheriff-courts, one at Inverness, one at Fort William, one in Sky, and one in the Long Island. There are about 57 freeholders in the county, who return one member to represent it in parliament.

Druidical circles are numerous in the county, as well as those appearances denominated vitrified forts. (See Forts Vitrified.) At Glenelg, in the Aird, and at Dalchullay in Badenoch, are the remains of very singular ancient buildings, composed of large stones, nicely adapted to each other, without cement, supposed to have been Pictish or Danish alarm posts. The royal castle of Inverlochy, near Fort William, had once a thriving burgh attached to it, called by some of the old historians, the empirium of Scotland. The town now in ruins, is a quadrangular building, with round towers at the angles, the whole area included within the outer ditches being nearly an acre and a half. The league between Charles the Great of France, and Achains king of Scots, is said to have been signed here about the end of the eighth century. Urquhart castle, once a royal fort, capable of containing 600 men, but now a ruin, stands very picturesquely on a rocky point projecting into Loch Ness. It was reduced in 1303 by Edw. I., and, in 1334, Robert Lauder, the governor, maintained it against the English, then espousing the cause of Edward Baliol. The castle of Invergarry was burned in 1746; its ruins are situated on a bold rock, rising from the side of Loch Oich. Besides these, there are many other castles of inferior note. Loch Moidart, on the west coast, is famous for having been the landing place of the young Pretender in 1745; and Culloden Moor, well known as the scene of his final defeat, on the 16th April 1746, lies on the flat and lengthened ridge of a hill about a mile from Inverness. The graves of the slain are distinguished by rising green from amidst the brown heath. We are not disposed to class what are called the parallel roads of Glen Roy, under the head of antiques, as we conceive them to owe their origin to natural causes. (See Parallel Roads.)

The population of Inverness-shire, in 1811, was estimated at 78,336; it is much to be feared, however, that it has not been on the increase since that period. The sheep farming system, prosecuted with so much eagerness by many of the great proprietors, particularly by those on the western coast, has compelled the Highlanders to emigrate with their families to America, in bodies so considerable as to depopulate large districts.

Some of the great landed proprietors in this county are, the Duke of Gordon, the Earl of Moray, the Earl of Seafield, Lord M'Donald, Lord Cawdor, Fraser of Lovat, M'Donald of Clanranald, M'Leod of M'Leod, M'Intosh of M'Intosh, M'Donnell of Glenfarry, M'Pherson of Clunny, Chisholm of Chisholm, Cameron of Lochiel, &c. The whole valued rent of the county, as fixed by the commissioners at Inverness in 1601, amounts to about £ 72,836 Scots.

The difference which exists between the climate and character of the east coast, and that of the west, is productive of very different modes of turning the surface to account. The comparative flatness and dryness of the districts, which in many districts the former encourages agriculture, which in many districts is productive of very different modes of turning the surface to account. The comparative flatness and dryness of the districts, which in many districts is productive of very different modes of turning the surface to account. The comparative flatness and dryness of the districts, which in many districts is productive of very different modes of turning the surface to account.
account of an undertaking so interesting to the rural
account of an undertaking so interesting to the rural
account of an undertaking so interesting to the rural
account of an undertaking so interesting to the rural
economist; but we cannot pass it over without noticing
the outlines of it. The subject is a large, flat, alluvial
deposition, evidently formed by the river Spey, which
runs along the north side of it to enter Loch Inch. It
is bounded on the south side by the ground rising from
the valley, on the west, by the river Trommie, there
joining the Spey at right angles; and on the east by a
round hill, dividing it from Loch Inch. Extending
about three miles in length, it is, at its greatest breadth,
about three quarters of a mile, and contains about 650
Scots acres: It lies so level in its whole extent, that not
above three or four feet of fall could be obtained.
Numerous springs rising in the ground itself, and the wa-
ter of upwards of ten streams of different sizes,
discharging themselves into it from the hills on the south,
contributed to render it a morass, which, whenever the
Spey overflowed its banks, was converted into a large
sheet of water. A partial defence against the river had
been begun at the junction of the Trommie with the
Spey; but finding that this was quite ineffectual, Mr.
Grant began, in 1807, to carry a more substantial em-
bankment from this point, all along the edge of the
Spey, towards the junction of that river with the lake,
where it united it to the north end of the round hill,
already noticed as existing there. Beginning at the
lake, he cut a canal up through the opening to the south
side of the round hill, and continuing it up the south
side of the flat, and along the bottom of the high
ground, he in this way intercepted all the streams, and
compelled them to flow by the canal into the lake,
through a valve floodgate, so constructed, as to prevent
any regurgitation from its floods. Drains running dia-
gonally from the embankment, and discharging them-
selves into the canal, were cut across various parts of
the level, serving not only effectually to dry it, but also
to subdivide it. The whole length of embankment
following the sinuosities of the river, is about three miles
and a half, averaging six feet in height, and thirty feet
in base. The canal is about three miles in length, and
21 feet wide. The whole expense of the work was
about £2300, and the subsequent receipts about £500 per
annum. It is chiefly used as pasture; but from some parts of it there are cut very rich crops of
fine natural hay, chiefly forain. One field of 20 acres
has repeatedly given upwards of £6 per acre of rent;
which, when the high situation is considered, is per-
haps no where equalled in the kingdom. Mr. Mac-
pherson of Belleville also, has embanked a very con-
siderable extent on the north side of the river.
On the west coast, the agriculture of the farms con-
sists in little more than the culture of a few potatoes or
a patch of barley, on such small spots as can be dug
with the spade; nor would the moisture of the climate
admit of the secure harvesting of large crops of grain,
what is raised being generally housed in great covered
barns, having air holes through them. The riches of
this part of the county, depend on the immense flock-
s of sheep covering the many hills, now required to con-
stitute the large farms of individuals. £2000 or £3000
a-year, is not an uncommon rent for a single farm, the
extent of which may be many miles. The hills on this
side of the island are all beautifullly green, and this
fresh hue is manifestly increasing, by the constant pas-
turing of sheep. It must, therefore, be admitted, that,
however harsh may be the measures leading to a com-
 mencement of this system, it is unquestionably the mode
of employing the estates in the western part of the
country pointed out by nature as the best.

In the eastern districts many plantations have been
made, and those of very great extent; but it is to be
regretted, that, excepting near gentleman's houses,
the Scotch fir is the prevailing tree. Larch, however,
is now beginning to be more planted, and, from its
hardy nature and superior qualities, will probably soon
usurp the place of the fir in the planting of extensive
moors. The young woods are thriving with the ut-
most vigour. Much yet remains to be done, to cover
the country with woods, the great scale on which we
find all the features of nature in this country, demand-
ing much greater exertions to produce an equal ap-
parent effect than a tamper country would require, and
the scope being almost unbounded. On the west coast,
there has been as yet little or no plantation; but there
can be no doubt, that trees would thrive well enough
in such sheltered glens as could be spared from the
sheep pasture.

The cattle of Inverness-shire are chiefly of the Sky Live
stock, breed, low in stature, but remarkably handsome. They
are crossed on some farms by bulls from Dunrobin in
Sutherland, producing a larger description of animal;
and in the south west part of the county they are mix-
ed with those from Argyleshire. Galloway cows have
been introduced on some pastures, but chiefly for their
meat. The old indigenous breed of sheep, small, fine
wooled, and altogether white, are still very plentiful.
The Linton breed, with black legs and faces are the most
prevalent. But Cheviot sheep are becoming every
day more numerous; and if the sheep-farming system
is persevered in, the superior value of their wool, when
considered with reference both to the quantity and qual-
ity taken together, will probably in time banish all the
other races. Bakewell tups are sometimes used to cross
with; and a flock of Merinos were not long ago
introduced near Inverness. Goats, though formerly
reared in great numbers, are now rapidly decreasing.
The old native breed of horses, small, hardy, clean
limbed, and nimble, is by far the most numerous; but
in the eastern districts, the gentlemen and substantial
farmers, are at great pains to introduce larger draft
horses from the southern counties; and much attention
has been lately paid by them to the breeding of this
animal. Asses are hardly known. All kinds of poul-
try are reared in this county; and hogs begin now to be
in greater plenty.

Besides the manufactures mentioned in the article Manufac-
Inverness-
tures, we have hardly any to notice in the other parts
Of the county. At Newton, tiles and bricks are
made; and at Kingussie, a machine has been erected
for carding and spinning wool. But by far the most
important occupation is that of burning kelp, which
furnishes a very large revenue to some of the proprie-
tors on the west coast.

The salmon fisheries on the river Ness let for £1200 Fishings
per annum, and those of the other rivers in a ratio equal
to their comparative value: the fish are mostly sent to
supply the London market. The herring fishery, par-
ticularly where the fish are cured and exported, also
affords a considerable branch of commerce.

Fort George is situated at the northern extremity of Fort
the county, on a low point stretching into the Moray
Firth, the passage of which it commands. It was be-
gun to be built under the direction of General Skinner,
by the orders of the Duke of Cumberland, in 1747, and
cost £160,000 in the completion. The citadel occu-
pies fifteen English acres. The ramparts are washed
by the sea on three sides, and the ditch surrounding
the remainder can be filled at pleasure. It is well sup-
plied with water, has four bastions, 80 cannon, and contains barracks for 3000 men. Though a beautiful specimen of fortification, it is considered defective as to position; and is particularly assemblable from the east along the shore, under cover of a sandy bank. Fort Augustus, situated at the western end of Loch Ness, was built in 1730. It has the lake on the north, the river Tarf on the south-east, and the Eriish on its north-west side. It has four bastions, and barracks for 400 soldiers. It was taken by the rebels in 1746, but was afterwards deserted by them. Fort William stands at the eastern extremity of Loch Linhe. It was originally built during Cromwell's usurpation, when it occupied much more ground than it does now. It was rebuilt by King William on its present reduced scale, and is now of a triangular form, having two bastions, 15 twelve pounders, and some mortars. In 1746 it stood a siege of five weeks, which was at last raised, with the loss to the garrison of only six men killed and four wounded. These two last forts were adapted for nothing else, but keeping the undisciplined Highlanders in awe. They may now, however, be of some use as stations, for those who are to look after the Caledonian Canal, and to collect its imposts. (For an account of this great national work, see Inland Navigation.)

By the late exertions of the parliamentary commissioners for Highland roads and bridges, numerous and convenient communications have been opened between the different parts of this county. The roads are all carried on excellent lines, and executed in the most superior and substantial manner. The road up the north side of Loch Ness, cut through solid rock, is a grand example of what human industry can accomplish in overcoming natural difficulties. It is for the most part carried along the face of perpendicular precipices hanging over the lake. An enumeration of all the roads made in Inverness-shire under the direction of this body, would exceed our limits; we must, therefore, refer to the map, accompanying their last report to parliament on this subject: suffice it to say, that the total length of line, without including Sky, does not amount to less than 282 miles. The employment of such a number of hands as have been required to execute these roads, has tended in some measure to raise the price of labor; but it has also given a degree of dexterity to the workmen of the Highlands not formerly possessed by them, which will be of great future benefit to the country.

We intended, under the present article, to have given an account of the island of Harris, and the other smaller islands which belong to the county of Inverness; but we have thought it better to include the whole of these islands under the heads of Lewis, and the islands connected with it, (including Harris,) Sky, and Uist. (t. e. d.)

Inversion, in Music, consists in placing one of the notes of a consonance either an octave higher or lower than it is written, or had before been considered; by which means, the complements of the inverted notes to the octave are produced. On comparing the ratios of inverted notes with those of their originals, it will be found, that one of the terms remains the same, and the other term is either halved or doubled. (2)

Involution. See Algebra, vol. i. § 132.

Joan of Arc. See Arc.

Joannina, the capital of Albania, and, next to Salonika, Adrianople, and Widdin, the most considerable place in European Turkey. It is said to have been founded by Michael Lucas Sebastocrator, and by the despot Thomas, who conquered Amurath Bey, the general of Amurath II., in 1424. It stands on the west bank, and near the northern extremity, of a large lake; and is about two miles and a half in length, and, in some places, nearly a mile in breadth. The ground on which it is built begins to rise and to become uneven towards the north and west, and a triangular peninsula, jutting into the lake, and defended by fortifications, contains the residence of the pasha. There are two principal streets; one running nearly the whole length of the town, and the other cutting it at right angles, and extending to the fortress. Many of the houses are large and well built. The bazar, or the street inhabited by tradesmen, is well furnished with shops of a shewy appearance; and the bizzestein, or covered bazar, is of considerable size. There is a summer residence of the vizier in the suburbs, at the north-west end of the town, built in the form of a pavilion, in a very superior style; containing a large salon, floored with marble, and situated in the midst of a garden, which is filled with the fruit-trees of the country, but otherwise in a wild and tangled state.

The first view of Joannina, on the road from Arta, is extremely beautiful. The houses, domes, and minarets, appear glittering through groves of orange, lemon, and cypress trees; and the lake spreads its smooth expanse at the foot of the city, while the mountains rise abrupt and magnificent in its banks. The lake is about 10 or 12 miles in length, and three in breadth, stretching from north-west to south-east, and containing two woody islands, one of which, towards the south, is of considerable size. On the western side of the lake are seen a beautiful verdant plain, the whole line of the town, and a long succession of groves and gardens; and, on the north and east, a chain of lofty mountains, one range of which, running from north to south, called Tomorh, is the ancient Tomasus, and another, from north to south-east, called Metzovo, is the ancient Pindus, dividing that part of Albania from the plains of Thessaly. The southern extremity of the lake extends into a hilly country, and forms at last a small river, which discharges for a few miles before it reaches the marsh on the banks of the gulph of Arta; and, hence, by some geographers, has been improperly styled the ancient Achelous, which did not now into the Ambracian, but the Thesprotian Gulph.

The population of Joannina is computed at the lowest to be 35,000, of which one-tenth are Mahometans, and the remainder Christians, with a few Jews. The Greek citizens are considered as a distinct race from the inhabitants of the adjacent country, and are supposed to be descended from ancient settlers who had retired from Peloponnesus. They are remarkably industrious, and excel in works of embroidery. Except the priests, and a few persons employed by the pasha, they are all engaged in trade; and many of them have spent three or four years in the mercantile houses of Trieste, Genoa, Leghorn, Vienna, and Venice. They are, in general, well acquainted with the manners and languages of Christendom; and the town altogether affords a very safe and agreeable residence to travellers. The inhabitants are subject to tertian fevers during the spring and autumn seasons, which has been ascribed to the vicinity of the lake; and the islands in the lake are said to be visited with earthquakes, especially in the month of October.

The annual revenue, drawn from the city by the pasha, is said to be 250,000 piastres. A fair is held once a-year about a mile and a half from the city, and con-
IODINE.

IODINE. This word is of Greek etymology, and signifies a violet colour. It has been recently introduced into the French and English languages, for the purpose of being applied as a name for a chemical substance recently discovered. The description of that substance and its properties will now hold a prominent place in all systems of chemistry; but it is one with which the science has been enriched since our article Chemistry was published.

The following method, recommended by Dr. Wollaston, yields it more abundantly. After concentrating the aqeuous solution of the soluble parts of kelp, and separating from it all the crystals that can be obtained, the remaining liquid is to be poured into a clean vessel, and mixed with an excess of sulphuric acid. This is boiled for some time, during which process sulphur is precipitated, and muriatic acid is driven off. The clear liquid is then decanted off, and strained through wool. It is next put into a small flask, with a quantity of black oxide of manganese, equal to that of the sulphuric acid first employed. A glass tube, closed at one end, is fixed to the top of the flask, and heat applied to the bottom. The iodine is sublimed and crystallized within the tube. Soaper's black ashes yield it in large quantity.

This substance has all the interest of a newly discovered gas, and derives a further interest from being the second coloured gas known in chemistry; colour being a property possessed by none previously known, excepting the oxymuriatic or chloric gas. A volume of it of considerable diameter exhibits a beautiful and rich violet appearance.

In the solid state, it has the form of flat octahedral crystals, the axes of which are in the proportion of two, three, and four. The form which most frequently appears in a section parallel to the plane of the greatest and smallest axis, is a rhombic plate, bevelled at each of its edges by two narrow planes, inclined to one another at an angle of about 120°.

According to the experiments of Dr. Brewster, iodine possesses the property of polarizing, in two opposite planes, the light which it reflects, a property which is peculiar to metallic bodies.

Its fusing temperature, when pure, is 225°, and it is General volatilized at 347° or 356°; though it may be distilled properties over with water at 212°. Its odour resembles that of oxymuriatic gas, though weaker. It is soft and friable, and may be reduced to a fine powder. Its taste is acrid, and its action on the stomach poisonous. It gives a deep brown stain to the skin, which, however, is soon removed. Like the oxymuriatic acid, it destroys vegetable colours, though with less energy. It is soluble in 4000 times its weight of water, and communicates to it an orange-yellow colour. Its specific gravity at 62°F is 4.916.

Iodine is not combustible, and cannot be made to combine, by any direct method, with oxygen.

which their other pursuits demanded, from executing their design so speedily or so extensively as they hoped.

This substance is procured from kelp in the following manner. The kelp is treated with hot water till all its soluble parts are dissolved. The solution is then evaporated, and from the dry salt the substance in question is separated by sulphuric acid. The salt is put in a tubulated retort, deep, but not large. The beak of the retort, which ought to be short, is introduced into a large globular glass receiver, which has an opening to allow the air to escape. Concentrated sulphuric acid is poured on the salt, through the opening, which is then closed with a stopper. An active effervescence ensues, and a violet-coloured gas is driven off, which crystallizes on the inside of the receiver. This is the iodine. When raised to its vaporzic point of temperature, it is a violet-coloured gas. Below that point, it has the form of brownish black shining plates.

Iodine was at first erroneously reported that the iodine was obtained from the insoluble parts of kelp. It cannot be obtained from pounded kelp. The solution and crystallization seem to be indispensable pre-requisites to the operation.

The discovery of iodine was M. Courtotis, a manufacturer of nitre in Paris, whose attention was directed to the subject, in consequence of a corroboration to which the metallic vessels employed in the process for procuring soda from the ashes of sea-weeds were liable, the cause of which he investigated, and in the investigation discovered this substance. The leading investigators of its chemical properties have been M. Gay-Lussac and Sir Humphry Davy; both of whom have mingled their experimental inquiries with their views of the more recondite laws of chemical change. In the present article, it is our intention to give a plain and perspicuous account of the leading facts, without omitting to notice the most important and least intricate of the arguments connected with them.

M. Courtotis discovered iodine in the year 1811; and the discovery was announced to the Institute by M. Clement about two years after, viz. on the 29th of November 1813. The chief reason of this long delay seems to have been, that these two gentlemen had wished to ascertain previously the qualities of this new substance, but had been prevented by the attention

tunes for the space of a fortnight. On that occasion, all the tradesmen in the city are obliged to shift their shops, and to erect booths in the fair, resembling those of England, which are regularly arranged like streets, and thus afford a full view of the merchandise of the place. There are caps from Trieste, Leithorn, and Genoa; knives, sword-blades, gun-barrels, glass, and paper from Venice; some coffee and sugar from Trieste; gold and silver thread from Vienna. But the chief articles of importation are French and German cloths from Leipzig, which are purchased by all the richer Greeks and Turks of the neighbouring countries for winter robes and pelisses. English cloth is the most esteemed, but is seldom met with, on account of its high price; and the best of what is sold at the fair of Joannina, is not equal to the worst of English fabric. The articles of exportation are oil, wool, corn, and tobacco for Naples, and the ports of the Adriatic; spun cottons for the plains of Tricola; stocks of guns and pistols, embroidered velvets, stuffs, and cloths, for the inland consumption of Albania and Romelia. Large flocks of sheep are grown, and the hides of cattle and horses, from the hills of Albania, are collected also at this fair, and sold for the Ionian Islands. The balance of trade is in favour of Joannina, and is paid in Venetian sequins. See Hobhouse's Tour in Albania, and Holland's Travels in Greece. (q)
It has the property of combining with almost all the metals. In this, and some other properties, it resembles the oxyburnatic or chlorine gas; but much less heat is evolved than by the combination of the metal with this last-mentioned substance. One probable reason of this is, that iodine is previously in a solid state. From this property, however, Dr. Thomson classes it with chlorine and oxygen, under the title of supporters of combustion. In this particular, it is to be observed, it also resembles sulphur, which combines with metals with an evolution of caloric.

Potassium, during its union with iodine, emits a pale blue flame. The result of the union is a white compound fusible at a red heat, soluble in water, of an acid taste, and re-yielding the iodine when treated with sulphuric acid.

With iron, mercury, tin, zinc, and lead, it forms compounds, fusible at a moderate heat, and generally of bright colours. Most of these are capable of forming compounds with potash, from which sulphuric acid evolves the iodine.

Under water, zinc and iodine combine on the application of a moderate heat. 100 parts of iodine combine with about 26.225 of the metals. These metallic compounds are called iodurets. Iron is acted on in the same manner. The ioduret of iron is brown, and fusible at a red heat. Its solution in water is of a light green like the muriate, or what Gay-Lussac calls the chloruret of iron, from supposing that it is not a combination of a metallic oxide with muriatic acid, but of the pure metal with chlorine.

The ioduret of tin is very fusible. When in powder it has a dark orange colour. It was found by Sir H. Davy to possess the characters of an acid. It combined with the alkalies without depositing any oxide. The ioduret of antimony is like the preceding, fusible, and resembles it when in the state of powder. The iodurets of lead, copper, bismuth, silver, and mercury, are insoluble in water, a property in which they differ from those of the more oxidable metals.

There are two iodurets of mercury, the yellow and the red, depending on differences of proportion in the combinations. The yellow ioduret contains one half less iodine than the red.

The iodurets of the metals are decomposed by chlorine, which unites with the metals, and expels the iodine. When ioduret of potassium is heated in contact with chlorine, chloruret of potassium (the substance called muriate of potash) is formed, the violet gas appears, but soon unites with chlorine, and they form by their union a peculiar acid compound; but towards the end of the process, as the proportion of chlorine diminishes, the violet coloured gas again appears. Ioduret of silver gives similar phenomena. Iodine, however, appears to possess a stronger attraction for most of the metals than oxygen.

Charcoal has no action on iodine, either at high or low temperatures.

With sulphur, iodine forms a weak compound of a greyish black colour, radiated like sulphuret of antimony, and iodine is separated from it when distilled with water.

With phosphorus it combines in different proportions with the disengagement of heat without light. One part of phosphorus and eight of iodine form a compound of a red orange brown colour, fusible about 212°, and volatile at a higher temperature.

With 16 parts of iodine to 1 of phosphorus, a greyish black crystallized compound is formed, fusible at 84°, with 24 parts a black compound is obtained, partially fusible at 116°.

The iodurets of phosphorus exhalo, when moistened, acid vapours. These are an acid substance, bearing the same relation to iodine that muriatic acid does to chlorine; and those who still maintain that chlorine is a compound of muriatic acid with oxygen, and that muriatic acid is obtained from it by separating the oxygen, may consider iodine as a compound containing oxygen, and the acid produced from it as comparatively a simple substance, being deprived of the oxygen contained in the iodine. But in this case, as in the former, the presence of hydrogen is essential to the formation of acid from the alleged compound. This most commonly happens from the presence of water; and for this, among other reasons, Gay-Lussac and Sir H. Davy consider the chemical change induced as consisting in the union of a simple substance, chlorine in the one case, and iodine in the other, with hydrogen. Though fully aware of the difficulty of deciding this question in the present state of science, we shall adopt the phraseology and nomenclature which depend on the latter of these theories, and which are in conformity with the doctrines of chlorine and muriatic acid, as stated in our article Chemistry. We shall keep in view that an acid is obtained from iodine by combining it with hydrogen, and this we shall call the hydriodic acid. This indeed is a matter of fact, whether iodine is regarded as a simple or a compound body.

Hydrogen, whether dry or moist, has no action on iodine on the ordinary temperature; but when a mixture of it with iodine is exposed to a red heat in a hydrogen tube, they unite, and hydriodic acid is produced, which abates its present by giving a reddish brown colour to water. The cause of this colour will afterwards appear. In this process, 100 parts of iodine absorb only .349 by weight of hydrogen.

Hydriodic acid is produced most easily by means of Mode of ob- ioduret of phosphorus. In order to procure it free from any admixture of phosphuretted hydrogen, it is neces- sary to employ a compound in which the phosphorus does not exceed a ninth part. This ioduret was, in the experiments of Gay-Lussac, moistened with pure water, or, what is better, water containing some hydriodic acid previously formed. Another method is to put the iodine into a small tube, which is then to be reversed in mercury, and the air expelled from it; by introducing a glass rod which nearly fills it; after which the phosphorus is brought in contact with the iodine, by being made to rise through the mercury; the substances immediately combine and the hydriodic gas is disengaged, and may be collected, by putting the open extremity of the tube under a glass jar standing in the mercury. The gas, however, begins to be decomposed as soon as it comes in contact with the mercury. The iodine combines with the mercury, forming a greenish yellow ioduret. By agitating the mercury, this decomposition may be made to extend to the whole gas present, and a volume of hydrogen is left exactly equal to one-half of the hydriodic gas. The contact of zinc and potassium produces the same result.

Hydriodic acid is colourless, and has an odour its proper- similar to that of muriatic acid. Its taste is intensely acid. It saturates its own bulk of ammoniacal gas. Chlorine deprives it of its hydrogen, and reduces it to the state of iodine, while itself assumes the form of muriatic acid. This acid is denominated by Gay-Lussac hydriodic, being formed of chlorine and hydrogen, and this name represents the analogy subsisting between it and
Iodine.

The specific gravity of hydriodic gas is to that of air as 4.443 to 1000. Iodine and hydrogen combine in equal volumes to produce this gas, and, as the vapour of iodine is the heaviest we are acquainted with, being to that of oxygen as 15.621 to 1, and to that of hydrogen as 117.21 to 1, it does not take one hundredth part of its weight of the latter gas to be converted into an acid. On this part of the subject, Gay-Lussac takes occasion to illustrate his principle on the ratio of saturation, as being determined by the relative densities of bodies in the state of vapour. The facts, as applied to the well-known gaseous substances, were first pointed out by that philosopher, and the doctrine extended by him to all other bodies, though of course it can only be determined with regard to those which we find capable of being raised to the state of vapour in our experiments, and not to all of these, as the high temperature at which many of them are volatilized renders all manipulations on their vapour, for the purpose of ascertaining their specific gravity, unmanageable.

Hydriodic gas is partly decomposed by a red heat. By the presence of oxygen, the decomposition is rendered more rapid and complete, and water and iodine are the products.

Hydriodic gas has a very strong attraction for water; a very large quantity of the gas is absorbed by a very small quantity of water, imparting to it a great increase of density, and the solution when strong is smoking. The most convenient way of obtaining this acid in a liquid state is, to dissolve ioduret of phosphorus in water. Part of the water is decomposed, the hydrogen forming hydriodic acid, and the oxygen a portion of phosphorus acid. When heat is applied, the two acids are separated. Another and an easier method is, to pass sulphured hydrogen through water containing iodine. The hydrogen goes to form the acid required, and the sulphur is precipitated. Heat is then applied to drive off the excess of sulphured hydrogen, and a colourless hydriodic acid is procured, from which the sulphur precipitated to the bottom of the vessel may be decanted off. This acid, like the sulphurous, may be condensed by evaporation, and, till it is raised to 257°, the vapour which it loses is almost pure water. While under this temperature, therefore, it may be evaporated in an open vessel, or the liquid which distils over may be blown away. When raised to this temperature, it gives over an abundant quantity of acid, and it does not admit of being heated above 202° under the common atmospheric pressure. This is the boiling point of the acid; and, being comparatively high, it prevents it from being disengaged from any neutralizing base by the volatile acids.

When distilled, or even simply exposed to the air, it assumes a brownish-red colour, from a partial decomposition by the contact of oxygenous gas, which forms water with its hydrogen, and the iodine, which is then evolved, combines with the liquid acid. This change is assisted by light and heat. The property of absorbing and dissolving iodine is one of the most prominent that belong to this acid, and the iodine is not capable of being driven off from it by heat, as it may from a simple solution in water.

Hydriodic acid is rapidly decomposed by sulphuric and nitric acid, and by chlorine, which seize on its hydrogen, and the iodine is either precipitated in brown crystals, or exhaled in purple vapours. Chlorine is a delicate test of this acid, as the purple vapours instantly appear when it is dropped into any solution which contains it; but they are speedily re-

dissolved by the acid, and therefore the chlorine must be cautiously added. When heated with black oxide of manganese it affords iodine, and an hydriodate of the metal. With red oxide of lead it affords iodine and an ioduret of the metal, the oxygen of the oxide going to form an additional quantity of water.

Before we proceed further, it may be proper to state the meaning of some terms connected with this subject. Iodine and hydriodic acid have been explained. The compounds of the acid, with neutralizing bases, are called hydriodates. Iodine, as we shall find, may be combined with oxygen, and the compound possesses acid properties. This acid is called by Gay-Lussac the iodic, and the compounds which it forms by uniting with neutralizing bases, he calls iodates. Dr. Murray calls this acid the axiodyc, and its compounds axiodates. We shall adopt these last terms, as well fitted to keep the facts in mind, and capable of being adapted to any theory.

The combination of iodine with azote cannot be produced by direct experiment. Ioduret of ammonia must be first formed. We shall therefore describe the phenomena which iodine exhibits with ammonia, previous to the consideration of the other alkalis. It differs from these others by not containing oxygen, a circumstance which materially affects the characteristic results of the chemical changes. When ammoniacal gas is passed over iodine, a viscid shining liquid is immediately formed, of a brownish-black colour, which, in proportion as it is saturated with ammonia, loses its lustre and viscosity. This is an ioduret of ammonia. When dissolved in water, the hydrogen of the ammonia unites with one portion of the iodine to form hydriodic acid, and its azote unites with another, to form an ioduret of azote. Or this substance may be obtained directly, by ioduret of putting iodine in fine powder into an aqueous solution of ammonia. This ioduret is pulverulent, and of a brownish-black colour. It detonates from the smallest shock, and from heat. The flame is of a feeble violet colour. When delicately prepared, it sometimes detonates spontaneously. When this compound is put in potash, the azote is disengaged, and the same products are obtained as when iodine is brought in contact with that alkali.

Iodine undergoes no change on the contact of gas. Sulphurous acid, in water, part of the water is decomposed. Its oxygen converts the sulphurous into sulphuric acid, and its hydrogen the iodine into hydriodic. These cannot be separated by heat, for the temperature which volatilizes hydriodic acid decomposes, under these circumstances, the sulphuric, reproducing the original sulphurous acid and the iodine. While the liquid is distilled over, these are the two ingredients, and it is coloured by the iodine; but, when cooled in the receiver, it becomes the state of sulphuric and hydriodic acids in limpid mixture.

The action of iodine on the oxides takes place both on the outside and without the presence of water, but exhibits idee different phenomena according to this difference of circumstances. When brought in contact with the oxide of potassium produced by combustion, it combines with the potassium to form an ioduret, and the oxygen is disengaged.

Barytes, strontites, and lime, unite with iodine, without the evolution of any gas. The oxides of zinc and iron undergo no change. The iodurets of barytes, strontites, and lime, show strong alkaline properties when dissolved in water, and are considered by Gay-Lussac as subiodurets.

**IODE.**

When iodine and oxides are made to act on one another in contact with water, the water is decomposed, its hydrogen forms hydriodic acid with a portion of the iodine, and its oxygen combines with another portion to form oxiodic acid. This takes place with potass, soda, barytes, strontites, lime, and magnesia.

Iodine, when made to act on a concentrated solution of potass, is rapidly dissolved, and forms, as one of the results, a granular white precipitate, which is shown to consist of oxiodic acid, combining to form an oxiodate with potass; for this substance degrades on burning coals like nitre, giving out oxygen and becoming ioduret of potass. The solution consists of hydriodic acid of potass, containing iodine. It is of an orange yellow, but, when saturated with iodine, it is of a deep reddish brown. When it is evaporated, and heated to redness, an ioduret of potassium is formed. In the first part of this process, the oxygen, according to Sir H. Davy, is expelled from one part of the potass, to form the ioduret of potassium, and is united to another to form the oxiodate of potass. But Gay-Lussac's view of it, that water is decomposed, its oxygen serving to form the oxiodate, and its hydrogen the hydriodate, seems more completely conformable to the facts. Sir H. Davy, from his first experiments, conceived that iodine formed substances analogous to alkalies, by combining with the alkaline metalloids; for the compound produced by its action on solution of potass, even when it was in great excess, reddened turmeric paper, and rendered the colouring matter of violets green; but he afterwards found that this was owing to a small quantity of supercarbonate of potass which existed in the hydrate; and when the compound is treated with hydriodic acid, and heated to redness, so as to produce an ioduret, it loses this property, and acquires the taste of a neutral rather than an alkali. Concentrated soda produces similar phenomena: a deflagrating iodate is precipitated, and a hydriodate retained in solution. The case is the same with barytes, lime, and strontites, and their oxiodates have little solubility. Hence these salts are obtained in a state of considerable purity.

When peroxide of mercury is exposed to a heat between 140° and 212° in water and iodine, a super-oxidoate of mercury is formed, which is held in solution, and an oxiodate which is insoluble, and remains mixed with the red ioduret, which is at the same time formed. The oxiodic acid, in order that its properties may be ascertained, ought to be obtained in a state of separation from the bases with which it is combined in its formation. For this purpose Gay-Lussac adopted the following process: Upon oxidoate of barytes; he poured sulphuric acid, diluted with twice its own quantity of water, and heated the mixture. The oxiodic acid in this case, according to him, abandoned its earthly base, and combined with the water. A small quantity of the sulphuric acid continued mixed with it, in consequence of the strong affinity of oxiodic acid for barytes. Sir H. Davy, however, found reason to be dissatisfied with these results, as disguising the real properties of this compound; and he succeeded in producing one in a pure state, by bringing together iodine and euchlorine, (hydrioxymuriatic acid,) in the form of gas, at the ordinary temperature of the atmosphere. The resulting compound, when the other ingredients were driven off by heat, was a white semitransparent solid, of an astrignent and acid taste, and sufficiently heavy to sink in sulphuric acid. It is deliquescent; its aqueous solution may be evaporated to the consistence of a syrup, and, by the continuance of heat, may be reduced to the original solid compound. It detonates when heated in mixture with inflammable substances. The oxiodic acid obtained by Gay-Lussac differed from this, by containing a portion of sulphuric acid, which prevented that chemist from being able to procure it in a solid form, and led him to believe that water was essential to its constitution. This acid cannot be procured by the direct union of iodine with oxygenous gas.

Dry iodine, when presented to chlorine gas, rapidly absorbs it in a quantity less than one-third by weight, producing a compound which in some parts has a fine orange yellow colour; in others an orange red. The yellow parts contain the largest proportion of chlorine, and are the most volatile. The yellow compound is called, by Gay-Lussac, the chloruret, and the red the sub-chloruret of iodine. Both of them speedily dissolve in the air. The solution of the chloruret is colourless, when the excess of chlorine is driven off, and then the mutual saturation of the two constituents appears to be complete. These solutions are very acid, and destroy the colour of a solution of indigo in sulphuric acid. The chloruret receives from Sir H. Davy the name of chlorionic acid. When a solution of it is saturated with an alkali, the chlorine acquires hydrogen, and the iodine oxygen, so that a muriate and an oxiodate of the alkali are obtained. Such are the relative tendencies of these two substances. That of combining with hydrogen is greatest in chlorine, and that of combining with oxygen is greatest in iodine. Heat disengages part of the chlorine, and reduces the solution to a sub-chloruret. The solution of the sub-chloruret is more stable, and capable of being volatilized without decomposition.

We shall now describe the properties of the neutral salts formed by combinations of the acids of iodine and salifiable bases. First the hydriodiates, and then the oxiodiates.

The hydriodiates may, in general, be obtained by hydri-oxidating hydriodic acid with the bases. But those of potass, soda, barytes, strontite, and lime, may also be prepared, by treating iodine with these bases, and employing the methods already described for separating these salts from the oxiodiates, which are formed at the same time. The hydriodiates of zinc and iron, and in general of all the metals that decompose water, are obtained by dissolving the iodures of those metals in water, and applying heat.

The hydriodiates are not changed by sulphurous or muriatic acid, or sulphureted hydrogen. Chlorine, nitric acid, and concentrated sulphuric acid, constantly decompose them, and separate the iodine.

When a solution of hydriodiate of potass is made to hydri-oxidate, the oxygen of the potass and the hydriodic acid unite, according to Gay-Lussac, to form water, and crystals of ioduret of potass are formed; these are considered by that chemist as completely analogous to the compound of chlorine and soda, his chloruret of soda, the sodane of Sir H. Davy, and the muriate of soda of former chemists. That there is no alkali in these compounds, and that the appearance of alkali properties, neutralized by an acid, arises from the chlorine supplying the place both of oxygen and acid, though it contains no oxygen and possesses no acid qualities, is one of the striking paradoxes which the adherents of the old school find most difficulty in admitting, and which, in determining the plausibility of the two theories, seems to form a sufficient counterpoise to the curious coincidences in some other particulars by which the new doctrines are supported. Hydriodiate of potass is composed of

Hydroiodate of soda may be obtained in flat rhombohedral prisms of considerable size. These unite to form larger ones, terminated in echelon, and striated like crystals of sulphate of soda. They contain a large proportion of water of crystallization, and are very deliquescent. Heat drives off the water, melts the salt, and then renders it slightly alkaline. It does not sublimate so easily as hydroiodate of potassa. At the temperature of 57, 100 parts of this salt are soluble in a little more than 57 parts of water. When dried, Gay-Lussac considers it as an ioduret of sodium, comparatively the doctrine already mentioned, which makes the salt called muriate of soda a chloruret of sodium. Hydroiodate of soda is composed of

Acid ............... 100.
Soda ................ 24.728.

Hydroiodate of barytes crystallizes in fine prisms, like those of muriate of strontrium. These are very gradually decomposed by exposure to the air, and iodine is evolved. They are faintly deliquescent, but have great solubility in water. They bear, without change, a very strong heat; and heat neither melts this salt, nor alters its state of neutralization; but, if oxygen is made to play on its surface when thus heated, vapours of iodine are evolved, and the salt becomes alkaline. A red heat, according to the opinion of the chemist just mentioned, converts it into an ioduret of baryum. Hydroiodate of barytes is composed of

Acid ............... 100.
Barytes ............. 60.622.

The hydroiodates of lime and strontrium are very soluble. That of lime is also very deliquescent, and has a bitter taste, similar to that of the muriate of lime.

Hydroiodate of ammonia may be formed either by combining equal volumes of ammoniacal and hydriodic acid, or by saturating the liquid acid with ammonia. It possesses nearly the volatility of muriate of ammonia, but it is more soluble and more deliquescent. It crystallizes in cubes. The hydroiodate of magnesia, formed by uniting its constituents, is deliquescent, and crystallizes with difficulty. When heated to redness, the acid abandons the magnesia, in the same way as takes place with the muriate of this earth.

The hydroiodate of zinc is obtained by putting iodine in water with an excess of zinc, and applying heat. This salt is extremely deliquescent, and scarcely crystallizable by evaporation. Heat deprives it of its water, then melts it, and sublimes it in fine prisms. If this is performed in close vessels, the salt is not decomposed; but air, when admitted, disengages iodine, and oxide of zinc is left behind. This hydroiodate is composed of

Acid ............... 100.
Oxide of zinc ........ 32.332.

When a solution of hydroiodate of soda, or potassa, is mixed with a solution of the salts of manganese, nickel, or cobalt, no precipitate is obtained; which shows that the hydroiodates of these metals are soluble.

The hydroiodate of soda, however, gives metallic precipitates with the salts of copper, lead, mercury, silver, and bismuth. That of copper is white, that of lead a fine orange-yellow, that of protosulphide of mercury, greenish-yellow, that of per-oxide of mercury orange-red, that of silver white, that of bismuth chestnut-brown. These are considered by Gay-Lussac, not as consisting of hydriodic acid and the oxides, but of iodine and the metals, and he therefore calls them metallic iodurets.

Those chemists who adhere to the old opinions, and apply them to the substances now under consideration, will not allow that there is any difference corresponding to these terms, because they consider iodine as a combination of the acid with oxygen.

All the hydroiodates have the property of dissolving ioduret of potassa, and forming a large quantity of iodine, which imparts to them a hydriodic-acid deep reddish-brown colour. It is separated from them by boiling, or exposure to the air in a dry state. This seems to be a simple solution, and not attended with any saturation of properties.

The oxide distillates of the alkalis, as was already mentioned, were formed along with the hydroiodates, when iodine and the alkalis are made to act on one another in water. In order to obtain these salts in a state of absolute purity, it is necessary to boil them repeatedly in small quantities of alcohol of a specific gravity from 8.6 to 9.2, which dissolves the hydroiodates, but not the oxide distillates.

Oxidate of potassa may be obtained in small crystals, of nearly a cubic form, which are not altered by exposure to the air, and deflake on burning coals like nitre. They require 13 1/4 times their weight of water to dissolve them. They require for their decomposition a heat somewhat higher than the hyper-oxygenmuriates. Oxygen is disengaged, and ioduret of potassium (or hydroiodate of potassa) remains, which forms a neutral solution in water. This decomposition affords the following proportions of constituents:

When we consider the potassium as oxidated, viz. in the state of potass, the portion of the oxygen which belongs to it is 3.773. The proportions, according to this distribution, therefore, will be

These two last numbers give the proportions of iodine and oxygen, which form oxydride acid, which are as 10:31.321.

Oxidate of soda crystallizes in small prisms, united Oxidate of in tufts, or in small cubic grains. They deflake on soda, hot coals, below a red heat, giving out a very little iodine. They are nearly of the same solubility in water as the former. When decomposed by heat, they afford,

On putting iodine into a solution of soda, till the liquid begins to be coloured, fine crystals, in six sided prisms, may be obtained by evaporation. These are very alkaline, and deflake on burning coals. They are very soluble, and contain a large quantity of water of crystallization. When soda is added to a neutral solution of oxidate of soda, a salt is obtained in smaller crystals, or silky needles united in tufts. They are not altered by the air. Both the oxide and the hydriodic acids have a great tendency to form subiodates.

The oxidates of potassa and soda detonate feebly by percussion when mixed with sulphur. It is not probable that they could be advantageously employed in the manufacture of gunpowder; 100 parts give only 22.59 parts of gas, whereas 100 parts of nitre give 53.62. This disadvantage would require to be compensated by a greater rapidity of detonation.

Oxidate of ammonia can only be obtained by sus-
Iodine.

The concurrence of properties which we find in iodine, and its various states of chemical combination, is curious and singular. "In its specific gravity," says Sir H. Davy, who considers it as an undecomposed body, "in lustre, the high number in which it enters into combination, and in colour, it resembles the metals. But in all its chemical agencies it is more analogous to oxygen and chlorine; it is a non-conductor of electricity, and possesses, like these bodies, the negative electrical energy with respect to metals, inflammable and alkaline substances; and hence, when combined with these substances in aqueous solution, and electrized in the voltaic circuit, it separates at the positive surface: but it has a positive energy with respect to chlorine; for, when united to this substance to form a compound acid, it separates from it at the negative surface. It has a stronger attraction for most of the metals than oxygen, but oxygen expels it from phosphorus and sulphur. Under a red heat oxygen converts the ioduret of phosphorus into phosphoric acid, and evolves the iodine. Its saturating powers seem to be greater than those of oxygen, and less than those of chlorine. It agrees with chlorine and fluorine in forming an acid with hydrogen; and it agrees with oxygen in forming an acid with chlorine."

One of the best tests of iodine is to be found in its Test property on silver, which has the advantage of制造业 by Sir Davy, in setting its presence in whatever state of combination it may be found. Water, when it contains less than one-thousandth part of its weight of a hydriodate, or oxiodate, tarnishes polished silver. This effect may be distinguished from that produced by compounds containing sulphures, or sulphureted hydrogen, by this circumstance, that the latter by being boiled with a little muriatic acid, are deprived of the power of tarnishing the metal, whereas solutions containing iodine, when treated in the same manner, still retain it.

In the experiments made by Sir H. Davy on natural productions which might be supposed to yield iodine, he found that the fusa and ulva of the Mediterranean afforded it in smaller quantities than the set de mare; and it was only in a few cases that he could find in them any traces of its existence. Slight traces of it were found in the Fucus cartilagineus, the membranaceus, rubens, and filamentosus, and in the Ulva pavonia and Ulva linea, but none in the ashes of the co-rallines and sponges. He examined some specimens of alkali, formed by the combustion of maritime vegetables which are not submarine, but found in them no decided indications of iodine. Yet he failed in his attempts to obtain it from sea-water, though the use of the volatil battery afforded some obscure results. The products separated at the positive pole were collected in a small cup of gold, covered with cement, except in the interior and lower part; and this, when exposed to the negative pole of a voltaic apparatus, yielded a black powder fixed in the fire, not unlike the compound formed by heating iodine and gold together; but it was too minute to admit of chemical analysis, in order to ascertain that it was not the same as is obtained by negatively electrifying the oxyanuret of gold.

See the Memoir of Gay-Lussac on Iodine, in the Annales de Chimie; or the English translation of it in the fifth and sixth volumes of Thomson's Annales de Philos- phy; and the two Memoirs of Sir Humphry Davy on the same subject, in the London Philosophical Transactions for 1814, parts i. and ii., which are republished in Tilloch's Philosophical Magazine; and an additional Memoir in the Transactions for 1815, part ii. (H. D.)
JOHANNA, one of the Comoro islands, lying in the northern part of the Mozambique Channel, which separates Madagascar from the coast of Africa. Its proper name is Ilincuan, which is said to have been progressively corrupted into Anzuan, Anjuan, Juanny, and Johanna. This island is in an equilateral triangular figure, each side extending, as we conceive, about eight miles in length; and its superficial area is computed at 162 miles. There is a bay with good anchorage on the north, though currents run with considerable force; and hither European vessels repair for the purpose of obtaining provisions and water. The island is mountainous, having in general a bold shore, and is visible from a great distance. A lofty peak rises amidst hills, which are clothed with wood and beautiful verdure. Numerous vallies, each watered by a stream, are interspersed among them, and their margins covered with groves of cocoa trees, mangoes, oranges, and citrons. Nothing can be more picturesque than the island of Johanna from every point of view. A volcano seems to have been anciently in activity here. Volcanic productions are universally disseminated; ferruginous particles are found in several places: flints are common on the shore, some parts of which also consist of a sandy bench.

This island abounds in great variety of the finest and most useful vegetables. Every gorge among the mountains, at a short distance from the sea, is compared to a well watered garden. In addition to the fruits already named, many others of the tropical climate grow in profusion. Roots are plentiful; the sugar cane attains much perfection; and wild indigo is copiously diffused. The henna, with the juice of which the natives stain their skin, is a shrub reaching the height of six or eight feet, though perhaps not indigenous to the island.

No venomous creatures are found here; but mosquitoes are extremely troublesome. Fish are not particularly abundant, at least at certain seasons, which has been ascribed to the presence of sharks. When they do appear, they are caught with lines, or speared as in dexterously rising on the surface. Turtle doves (one species of which is of a beautiful grey, shaded with green, blue, and white,) and quails are numerous: the guinea fowl is less so, but is said to be remarkably tame; and there are multitudes of a kind of hawk which subsists on fish. A species of brown monkey is the chief wild animal inhabiting the woods; swarms of mice infest the fields, and are supposed to be detrimental to the crops. The only domesticated quadrupeds are goats and the Indian cow, which find excellent pasture in the vallies.

The inhabitants of this island are of two different kinds, Africans and Asians, distinguished by prominent features. The former are the same as those dwelling on the neighbouring coasts; the latter have sprung from a colony of Arabsians, by whom the island was conquered, and who still hold it in subjection. These constitute the higher ranks, and the others the lower. But from the intermixture that unavoidably takes place among mankind in the course of successive generations, the original character of each is much obliterated among many of the natives, unless in the family of the sultan, where it is still preserved pure. The Arabic language is in general spoken; and, from the frequent visits of European vessels, both English and French are tolerably well understood, and even employed in conversation by the natives. The men in general testify much good sense and acuteness; many embellish their discourse with poetical phrases; and great politeness is practised in their address. They are of a courteous and affable disposition, extremely hospitable to strangers, whom they receive with extraordinary demonstrations of friendship; nor are these external only, for numerous examples might be given of their afflicting success to shipwrecked mariners, when they could entertain no expectation of any return. Their honesty is remarkable, and those who have provided supplies to European vessels, are anxious for certificates of their conduct. These people are nevertheless indolent, excessively jealous of their women, and far from being endowed with much personal courage. Perhaps the last ensues from their constant exposure to the attacks of a ferocious enemy of superior force, which cannot but damp the spirit of resistance. Women of the lower ranks withdraw from the gaze of the men, and those of the higher are seldom or never seen by strangers. But those English ladies whose curiosity has gained them access to the harem, report that they are handsome, richly attired, and display a profusion of ornaments.

Marriages are celebrated with music and dancing, the former produced by the Mozambique violin, drums, and shells. Sometimes there is singing by male voices, when the burden of the song is repeated by the whole company present. Sir William Jones was assured, that songs were composed in the island. The dances resemble those of Madagascar, sometimes exhibiting intricate movements, but in general distinguished by contortions accompanied by grimaces, more than by graceful action. At the close of every dance, a few pieces of money are thrown at the feet of the musicians. Meanwhile the new married female sends presents of flowers to strangers from the place of concealment, where she and her friends behold what passes. On the celebration of a marriage, the husband invites all his friends and relations to feast and dance during eight successive days, beginning at four in the afternoon, and continuing until morning. The guests, however, according to their ability, contribute towards defraying the expenses.

The inhabitants occupy themselves in agriculture, some holding considerable estates in the interior. Several practise the mechanical arts, though, from the rudeness of their tools, the workmanship is coarse; and shops of goldsmiths, weavers, and the like, are to be seen. The unsettled state of the country, however, is very prejudicial to agricultural pursuits. Probably they construct their own vessels, which consist of small canoes hollowed from the trunk of a tree, and war boats capable of carrying 200 men. In their large banks they undertake long voyages, sailing as far as Bombay and Surat, or to the Isle of France; but they seem to have little productive trade; for notwithstanding the beauty and fertility of their island, it seems to have few commodities which are desired by other nations. Arms and ammunition, knives, cloth, and cotton, are purchased at Bombay; ivory is obtained from Mozambique; rice, a kind of bread-fruit, and cattle; from the rest of the Comoro islands. Some of the chief men make expeditions to the African coast for the purchase of slaves; the humanity of which traffic they defend on the same principle as other dealers, namely, that the objects of it would otherwise suffer death: and others are purveyors to the European vessels that anchor on the coast.

Almost all the natives of Johanna profess the Mahometan religion; but it is asserted, that fetishes, that is, animals or inanimate bodies, are venerated by the lower
orders; and it is related, that there is a small lake among the mountains of the interior, which is held sacred, as well as the water-fowl that frequent it. The higher ranks and clergy are not entirely destitute of learning, and they possess some books among them, apparently for the most part theological.

The government of the island is monarchical, elective, (though the right is not known to have been exercised,) and aristocratic. The extent of the Sultan's power is not explained; he is obliged to obtain the sanction of his chiefs to certain acts, such as the declaration of peace or war; and the latter are said to defray its expense by a voluntary contribution, in return for which they claim all the booty. Profound respect is entertained for the person of the Sultan; none of the inhabitants can address him unless kneeling, and having touched the ground with their foreheads. He never goes abroad but when accompanied by several chiefs and domestics, of whom one carries his betel box, other two his lances, a fourth precedes him blowing a shell, and a considerable retinue of the populace is in attendance. The charges of government are defrayed by a tax from the villages. Formerly the other Comoro islands were subject to the Sultan of Johanna, and the present prince still claims the sovereignty of them, and the vassalage of their chiefs; but it is very doubtful how far he receives any tribute. Females are not excluded from the succession.

The principal town of the island is Machadon, or Matsanudo, on the north coast, near the bottom of a mountain. It is surrounded by walls fifteen feet high, flanked by square towers, and is said to be a mile and a half in circuit. But the streets are narrow and irregular, resembling so many lanes, and the houses poor both within and without. They are commonly ranged around a small interior court. The first apartment is open, and beyond the court is that of the women. In the former, the place for repose is separated by a chintz curtain from the rest of the room, and elevated in an angle several feet high. It is composed of successive broad steps, whereon one or two persons can rest. The middle of the apartment is appropriated for meals, where the guests either sit on low stools, or recline against the steps of the bed-place. The houses of the chief men, however, are capacious, but scantily furnished. That of the king, which cannot merit the name of a palace, differs from the rest in having a more spacious vestibule, and a long gallery hung round with musquets and powder horns, serving both for a hall of audience and a kind of arsenal. At one end are three large windows within a balsoitra, where also is an arm chair, occupied as a throne, by the sovereign. Sir William Jones describes an apartment wherein the sultan received him, as 'hung with old red cloth, and decorated with pieces of porcelain, and festoons of English bottles; the lampes were placed on the ground in large sea shells; and the bed-place was a recess, concealed by a chiffon hanging opposite to a sofa.' The houses are so much impregnated with the odour of musk, for which the natives entertain a remarkable partiality, as to be exceedingly disagreeable. Machadou contains a mosque, a small mean edifice, surrounded by a minaret, where several Arabsians are always to be seen in prayer. It was built by a female sovereign of the island, named Halimah, or Alima, who probably reigned two centuries ago; but is now becoming ruinous. The fort commands the town, and being elevated high above it, at first sight presents an imposing appearance. It is gained by flights of 300 or 400 steps included between two walls. The country is rather arid in the immediate vicinity of Machadon; but the climate is very fine, and the people healthy. Some nevertheless labour under severe distempers. Fevers and dysentery are the most common complaints; and it is much to be doubted whether the climate is equally salubrious to Europeans.

Another town, said to have been named Johanna, stood on the eastern coast seven leagues from Machadon, in a picturesque situation. It was sacked in 1790 by the natives of Malagascar, who make frequent descents on the Comoro islands, and always commit terrible ravages. Their very name makes inhabitants tremble, and in general they never go unarmed.

Very different statements have been given of the population of Johanna. Grose states it at 130,000, which exceeds all probability. Captain Williamson in 1810, computes it at 50,000 or 100,000, which at a medium would allow 581 persons to each square mile; and Sir William Jones speaks of taxes being levied from 200 villages. But late calculations, apparently much more authentic, reduce the population to 6000 or 7000.

The history of Johanna is obscure. It is supposed that the Comoro islands were peopled originally from Africa, and that the Arabsians established themselves here in the twelfth century. In the year 1600, Captain John Davis found Johanna governed by a queen; and fifteen years later, Sir Thomas Roe and Captain Peyton remarked, that the dominion of a female extended over all the islands; but he seems to place her residence on Mohilla, one of their number. Sidi Ahmed ruled Johanna in 1783. But the same Sultan who, in 1788, is represented as being 65 years of age, and having occupied the government for 40 years. His manners were dignified, and his courtesy to strangers of the most engaging description; but the island was visited by many misfortunes during his reign, and he is supposed to have survived the sack of Johanna only a short time. He was succeeded by his eldest son Missolin, who died in the year 1797, leaving a son Ahmed under the regency of his brother. During the minority of this prince, 33 Frenchmen, some of whom had distinguished themselves in the revolution that agitated their own country, were banished hither, and landed under the ostensible pretence of assisting in the defence of the island. In 21 days no less than 20 died: the survivors embarked for Comoro, 25 leagues distant; but owing to accidents and other causes, they successively perished, so that not one survived in 1804, only a year after their first arrival. The regent having formed a plan for the destruction of the young prince, which proved abortive, fled to Muckat, where he in vain sought the aid of the Imam.

Lat. 12° 4' N. Long. 44° 34' E. (c)

JOHNSON, SAMUEL, an eminent English author, was born at Litchfield, in Staffordshire; on the 18th of September, (n. s.) 1709. His mother, Sarah Fowle, was descended of an ancient race of substantial yeomanry in Warwickshire. His father, Michael Johnson, was a bookseller and stationer in Litchfield. He was a man of a large robust body, and of considerable mental attainments; but not without that morbid taint of melancholy which his son inherited. It seems to have been from him, and not from his nurse, as has been elsewhere stated, that our author received the tinge of scorbutica, which disfigured a countenance naturally well-formed, and hurt his visual nerves so much, that he did not see with one of his eyes, although its appearance was little different from that of the other.
His mother, yielding to the superstitious notion which so long prevailed as to the virtue of the royal touch, carried him to London in his childhood, where he was actually touched by Queen Anne. The faint remembrance of this circumstance always remained in Johnson's mind. Being asked, if he could remember Queen Anne? He said, he had a confused, but sort of solemn recollection, of a lady in diamonds, and a long black hood.

He was first taught to read English by a woman, who kept a school for young children in Litchfield. When he was going to Oxford, this humble instructor of his childhood came to take leave of him; and, in token of her kindness, brought him a present of gingerbread, saying, that he was the best scholar she had ever had. He delighted in mentioning this little compliment; adding, with a smile, "that this was as high a proof of his merit as he could receive." His next instructor in English was one Brown, who had published a spelling-book, which he dedicated to the universe, but of which Dr. Johnson was afraid that no copy was to be found. He learned Latin at a school at Litchfield under a Mr. Ifunter, a severe disciplinarian, but an attentive teacher. Johnson owned, that he had himself required the rod; and to that instrument of tuition, it was a part of his principles to pay the most profound deference. Once, when he saw some young ladies who had been remarkably well brought up by a severe mother, he exclaimed, "Rod, I will honour thee for this thy duty." The mind that can dwell with satisfaction on the associated ideas of a rod and the tender frame of a young virgin, must have its sensibilities oddly constituted. At school, though he was too short-sighted to join in the generality of boyish amusements, he maintained the same ascendency over his playmates that he kept up, in after life, in the circles of literature. His proficiency was also then, as in every other period of life, much beyond his apparent diligence. He was impatient of stated tasks, but could rouse himself to great exertions. His memory was prodigiously tenacious. When a boy, he was inordinate fond of reading romances. To those extravagant fictions he was once heard to attribute the unsettled turn of mind which prevented him from ever fixing in any settled profession. The circumstance of his reading many romances in his youth is not wonderful, for that species of reading was more common in the last than in the present age. However the reading for pleasure revived as a species of black-letter learning; it was then the ordinary food of young minds, before they encountered more serious erudition.

After having resided for some time at the house of his uncle Cornelius Ford. Johnson was, at the age of 15, removed to the School of Stowbridge in Worcestershire, of which Mr. Wentworth was then master. Here, according to his own account, he was rather irreverent towards a severe master, whom he did not on the whole esteem, but in after life disposed to make allowance for his castigations of him, and to reflect on how much he had taught him. He remained at Stowbridge about a year, and then returned home, where he stayed for two years, reading in a very demaitory manner, but with such ultimate advantage, as to go exceedingly well qualified to the university. It might perhaps, as Mr. Boswell justly remarks, have studied more assiduously, but it may be doubted whether such a mind as his was not more enriched by roaming at large in the fields of literature. The analogy between the body and mind is very general, and the parallel will hold as much as to their food as to any other particular. The flesh of animals who feed exclusively, is allowed to have a higher flavour than that of those who are coped up. May there not be the same difference between men who read as their taste prompts, and men who are confined, in cells and colleges, to stated tasks. By what means his father was enabled to undertake the expense of sending him to the university, has not been very accurately told. He had once realized a good deal of money in trade, but had afterwards lost it, by embarking in a ruinous speculation, and was at this time in narrow circumstances. It is believed that one of his schoolfellows undertook to support Johnson at Oxford in the quality of his companion, though he failed in rendering him the promised assistance. He went, however, to Oxford, and was entered a commorner of Pembroke college on the 31st of October, being then in his 19th year. His tutor was a Mr. Jordan, whom Johnson respected for his personal worth, but not for his abilities. Having absented himself from this preceptor for several days, Mr. Jordan asked him the reason of his absence. Johnson told him he had been sliding in Christ Church meadows. Mr. Boswell, to whom he related this answer, remarked, that it shewed great fortiitude of mind. "No, Sir," said Johnson, "stark insensibility."

In his 20th year, while he was at Litchfield during the college vacation, his constitutional melancholy assayed a peculiarly gloomy aspect, and on his return to the university, the unequal state of his spirits, and probably too real causes for depression about his future prospects, seem to have made him an irregular, and by no means an exemplary student. He was often seen lounging at the college gates with the younger students, whom he amused by his wit, and spirited up to contempt of their superiors by his satire. Dr. Adams, his nominal tutor, after Norden, at Pembroke college, said, that while he was there, he was a gay and frolic-some fellow. When the remark was imparted to him by Boswell, "Ah Sir," he said, "I was mad and violent; I was miserably poor, and thought to fight my way by my literature and my wit." Poverty at length compelled him to quit the university without a degree. He returned to Litchfield, in 1751, with very gloomy prospects. His father died a few months after his return, and the little he left him was barely sufficient for the temporary support of his willow. In the following year, he accepted a place of usher of the school of Market Bosworth in Leicestershire, an employment which the insolence of the patron of the school, Sir Wolstan Dixie, with whom he was obliged to live, made him speedily resign, and always remember with a sort of horror. After this he resided for six months at Birmingham, as the guest of his old school-fellow, Mr. Hector, an eminent surgeon, in whose house he translated and abridged Father Lobo's "Voyage to Abyssinia." For this task he received five guineas. The body of the work is written with no remarkable elegance or power, but the preface has some passages that are full of his characteristic manner.

In 1754 he returned to Litchfield, and there issued proposals for an edition of the Latin poems of Politian, with the history of Latin poetry, from the era of Petrarch to the time of Politian, together with a life of Politian. The subscription, however, was not enough to encourage him to proceed. Disappointed in this scheme, he offered his services to Mr. Cave, the proprietor and editor of the Gentleman's Magazine. On this occasion he suggested some improvements in the ma-
nagement of the Magazine, and specified the articles which he was ready to supply. Cave answered his letter, but it does not appear that any agreement was formed between them at this time. At this period, in his 25th year, when his finances must have been very low, and his prospects very precarious, he adopted that happy mode of extricating himself from his difficulties, to which men of genius often resort, that of taking to himself a wife. His choice was a Mrs. Porter, the widow of a mercer in Birmingham, who was in her 48th year. In spite of this disparity of their ages, Johnson greatly told his friend, Mr. Topham Beauclerk, who archly repeated it, “that it was a love marriage on both sides.” His bride had a fortune of eight hundred pounds; and with part of this money he hired a house at Edial, near Lichfield, where young gentlemen were to be boarded, and taught the Greek and Latin languages. The scheme, however, did not succeed. In the space of a year and a half he had only found three pupils, one of whom was David Garrick. During his residence at Edial, he wrote a considerable part of his *Irene*, which his friend Gilbert Walsley, registrar of the ecclesiastical court of Lichfield, a man of letters and generosity, advised him to prepare for the stage.

Finding his academy so unlikely to succeed, he determined to repair to London, and there to try his fortune. Garrick, his pupil, had formed the same resolution, and, in March 1737, they arrived in the metropolis together. One of his first employments in London was to proceed with the composition of his tragedy. He also renewed his application to Cave, by whom he was employed in translating the history of the Council of Trent, and for the part of the work which he executed, he received £ 49; but it was dropped upon the announcement of a rival translation. In the course of the summer he went back to Lichfield, where he had left Mrs. Johnson—finished his tragedy, and returned at the end of three months, with his wife to London, where he endeavoured to prevail on Fleetwood, the patentee of Drury Lane, to accept it. Being unsuccessful in this attempt, he resumed his literary drudgery, and became a principal contributor to Cave’s Magazine. For that work he supplied, among many various articles, the debates in Parliament. These were given under the fiction of debates in the senate of Lilliput, and the speakers were disguised under feigned names. Guthrie, a writer of history, for a time composed these speeches from such heads as he could bring away in his memory. Johnson first assisted in this department, and then entirely filled it. The public was highly delighted with the extraordinary eloquence which Johnson displayed in these compositions, which were almost exclusively the product of his own invention. In process of time he came to consider this deceit as an unjustifiable imposition on the world. It is probable, however, that he generally adhered to the tenor of argument really employed by the parliamentary speakers, otherwise his account of the debates would scarcely have passed at the time for genuine. He owned that he was not quite impartial in dealing out his reason and rhetoric; but took care that the Whig dogs should not have the best of it. Mr. Chalmers, in his edition of the British poets, (Life of Johnson,) has announced his having made the discovery, that Johnson was at one time editor of the Gentleman’s Magazine, and had a regular salary of £100; but that must have been at some distance of time from his first connexion with the work. His apparent poverty, when he writes to Cave with the signature of *Imprunus*, seems to be with difficulty reconcilable to the supposition of his having held, at that early stage of his career, so considerable a settled income from his knowledge of Satire.

In the year 1738, he rose at once to public notice by the publication of his London, in imitation of the third satire of Juvenal. Dodson gave him ten guineas for the copyright of this poem, and such was the state of literary property at the time, that he considered it a liberal price. His London came out in the same morning with Pope’s “Seventeen hundred and thirty-eight.” The former poem immediately brought its unknown author a reputation, that made him be compared with the reigning bard of the time; and Pope himself was among the first to acknowledge its merit, and to predict his future consequence. It is at this very period when he could be said to have first begun to taste the only consolation of an author’s life—reputation, that we find him making serious efforts to settle himself in some other profession for a livelihood. He would have accepted of the mastership of the school of Appleby in Leicestershire, the salary of which was about £ 60 a year; but the laws of the school required that the candidate should be a master of arts, and the University of Oxford, when applied to for a degree, refused to grant it. In this unsuccessful effort for a degree, Pope interested himself in Johnson’s behalf; although he knew him only by name, as author of London. About the same time he formed a design of studying the civil law, with a view to practise in Doctor’s Commons. This scheme, also, was rendered abortive for want of a degree, and he was obliged to resume his labours in the Gentleman’s Magazine. His productions from this time became more numerous than it is possible to particularize in any condensed account of our author. He published, in 1739, an “ironical” vindication of the licencers of the stage, against the scandalous aspersions of the author of “Gustavus Vasa.” In the same year his attachment to the Tory, or rather the Jacobite party, was shown in an humorous pamphlet, entitled Marmor Noegoiiiencse, consisting of a supposed ancient prophecy in monkish Latin rhymes, with an explanation. For some years he composed biographical articles in the Gentleman’s Magazine, full of that animated and shrewd cast of language and thought, which he brought into English biography. His life of Savage, published separately in 1744, forms a sort of era in the record of his prose writings. He had been intimate with Savage for several years; and if we may judge of Johnson, by the circumstance of his living for a time separated from his wife, as well as by the poverty and midnight rambles in which Savage and he shared, it would appear that the moral biographer himself had been drawn, for a while, into the same follies, dissipations, and idleness, of his ill-starred brother genius. But the effect of his companionship on Johnson’s habits was not lasting, and, to his knowledge of Savage, we are indebted for one of the most interesting and instructive pictures of an individual mind that was ever exhibited. No one who has read the life of Savage, can have failed to acknowledge the eloquence with which he describes the sufferings of unfortunate genius, and the candour with which he traces his faults; whilst he throws a transparent veil of compassion and charity, that softens, without hiding, those vices that would offend us in closer view.

In 1745, he published miscellaneous observations on the tragedy of Macbeth, with remarks on Sir Thomas Hanmer’s edition of Shakespeare, to which he prefixed proposals for a new edition of the great poet, and was
probably engaged at times, during two years, in preparing for the undertaking, as, in 1745 and 1746, his periodical contributions to the Magazine were suspended. The notice of the public, however, was not excited to his anonymous proposals, for the execution of a task which Warburton was known to have undertaken; and the project, at least, at the present, though to revive at a future period. The year 1747 was remarkable, in his life, for the production of one of his best pieces of poetry, namely the prologue which he supplied to Garrick at the opening of Drury Lane theatre, and the undertaking of his grand work, a Dictionary of the English language. A plan of the Dictionary, written with uncommon comprehension, perspicuity, and precision, was addressed to the Earl of Chesterfield. The professions of Chesterfield as a Maccenas in this business, and his subsequent neglect of Johnson, are but too well known. The price for which Johnson agreed with the booksellers for his Dictionary was £1575. At the outset, he flattered himself that he should be able to finish it in three years, but it employed him, though many interruptions, for eight years. With a view to his undertaking, of his own expense, he hired a house in Gough Square, Fleet Street, where a room was fitted up for the amanuenses, who were to execute the laborious part of the business.

At intervals he exerted his talents in compositions very different from lexicography, and, probably anticipating easier circumstances from the credit with his booksellers which his compilation afforded him, he devoted a regular portion of his time to social amusements with selected friends. Of these he formed a club, that met at Horseman's Chop-house, in Ivy-lane, Paternoster Row, every Tuesday evening, with a view to enjoy literary conversation. The members, associated with him in this club, were his beloved friend Dr. Richard Bathurst, a physician; Dr. Hawkesworth; Dr. Salter; Mr. Ryland, a merchant; Mr. John Payne, then a bookseller in Paternoster Row; Mr. Samuel Dyer, a learned young man intended for the dissenting minister; Dr. McGhee, a Scotch physician; Dr. Edmund Barker, another physician; and Sir John Hawkins. The endowments of Dyer are represented by Sir John Hawkins as of so superior a kind, that Johnson might almost be said to have looked up to him. They used to dispute in this club about the moral sense and fitness of things; but Johnson was not uniform in his opinions, contending as often for victory as for truth. This failing attended him through life.

In January 1749, he published with his name The Vanity of Human Wishes, being the Tenth Satire of Juvenal imitated. Critics seem always to have the fairest right to establish comparisons between one work of an author and another of a similar nature. London and The Vanity of Human Wishes, have, therefore, been often compared. The general opinion has agreed, that there is more of the charm of common life in the poem London, and a higher tone of reflective moral eloquence in The Vanity of Human Wishes. The description of the scholar's disappointed hopes, in the latter poem, is peculiarly eloquent.

In the same year, his tragedy of Irene, which, to use his own phrase respecting one of Thomson's poems, might have been expected, in its long state of repose, to have gathered dust and harboured spiders, was brought upon the stage of Drury-lane by the kindness of Garrick. Sensibly as Johnson ought to have felt obliged to Garrick for his assistance, he at first resisted, with violent irritation, all the alterations which the manager suggested for adapting his piece for theatrical effect. "The fellow," he said of Garrick, "wants me to make Mahomet run mad, that he may have an opportunity of tossing his hands and kicking his heels." He was at last, with difficulty, prevailed upon to comply with Garrick's wishes, and to allow of some changes; but all these were not enough to bring the play upon the boards, but, though supported by the finest acting, and by every advantage of dress and decoration, it failed to captivate the public. Garrick's zeal, nevertheless, carried it through for nine nights; so that the author had his three nights profits; and Dodson gave him £100 for the copy right. When asked how he felt upon the bad success of his tragedy, he replied, "Like the monument." Such magnanimity is, probably, as rarely to be found, as the power of writing a tolerable tragedy.

In the year 1750, he came forward in the character for which he was eminently qualified, that of a declaimer on moral and religious subjects. The vehicle which he chose was a periodical paper, denominated, (with no great felicity of title,) The Rambler. This title has been ludicrously translated, in the Italian version of the work, literally, Il Fuggente. The first paper of The Rambler was published on Tuesday the 20th of March 1750, and he was enabled to continue it, without interruption, every Tuesday and Friday, till Saturday the 17th of March 1752, on which it closed. Many of those papers were written in haste, as the moment pressed, without ever being read over by him before they were printed. He received, in the course of the work, no assistance, except four billets in No. 10, by Miss Mulso, afterwards Mrs. Chapone; No. 30, by Mrs. Catherine Talbot; No. 97, by the famous Samuel Richardson, and No. 44, and 100, by Mrs. Elizabeth Carter. The first reception of The Rambler was not highly favourable. Its popularity was of slow growth.

In the following year, he was involved in the controversy that arose from Lauder's attack upon the memory of Milton. The history of Lauder's forgeries need not be here detailed. It may be necessary, however, to notice, that the extraordinary attempt of that impostor was no sudden effort.—He had brooded over it for many years; and, considering the difficulty of the task, came wonderfully well prepared for the execution of it. The depth and artifice of Lauder, and the seeming improbability of any man being capable of such gratuitous and unprincipled malice towards the memory of an author who had been fourscore years in his grave, form some apology for Johnson having been, in the first instance, the dupe of Lauder. Yet it is impossible to advert to the cheerful promptitude with which Johnson lent his pen to the first support of the forger, without a suspicion that he was well pleased at the prospect of Milton's reputation sustaining a reverse. Sir John Hawkins says, "he could all along observe, that Johnson seemed to approve, not only of Lauder's design, but of the argument; and seemed to exult in a persuasion that the reputation of Milton was likely to suffer by this discovery." Lauder, after having from time to time published his fabrications in the Gentleman's Magazine, ventured at last to collect them into a pamphlet, entitled, an Essay on Milton's use and imitation of the Moderns in Paradise Lost. To this pamphlet, Johnson wrote a preface, expressing a full conviction of Lauder's arguments. But the Rev. Dr. Douglas having clearly detected the impostor's forgeries, Johnson dictated a letter for Lauder, addressed to Dr. Douglas, and acknowledging his fraud in terms
of suitable contrition. Johnson's conduct has been praised for doing so.—He could do nothing less, unless he had deliberately resolved to consign his own character to infamy. Though his circumstances were at this time far from being easy, his humane and charitable disposition was constantly exerting itself. Mrs. Anna Williams, daughter of a very ingenious Welsh Physician, and a woman of more than ordinary talents and literature, having come to London in hopes of being cured of a cataract in both her eyes, which afterwards ended in total blindness, was kindly received as a constant visitor at his house while Mrs. Johnson lived; and, after her death, having come under his roof to have an operation upon her eyes performed with more comfort to her than in lodgings, she had an apartment from him during the rest of her life, at all times when he had a house. Three days after the conclusion of the Rambler, he lost his wife; whose loss there is every reason to suppose he felt as deeply as he deplored it. When he had recovered from the first shock of this event, he contributed several papers to the Adventurer, then conducted by Dr. Hawkesworth. His dictionary was now drawing to a conclusion; and Chesterfield, who had left him to struggle with difficulties during the compilation of it, now began to entertain the renewal of his acquaintance, with the hopes of the work being dedicated to him on its appearance. For this purpose he wrote two essays in the World, anticipating the high character of the dictionary, and sent a friend to sound Johnson on the subject of the dedication. Johnson, although he had once condescended to be indebted for £10 to his Lordship, treated the shrewd patronage of the peer with deserved contempt, and sent him that letter of rebuke which has been so often transcribed, containing these memorable words:—'The notice which you have been pleased to take of my labours, had it been early, had been kind; but it has been delayed till I am indifferent, and cannot enjoy it—till I am solitary, and cannot impart it—till I am known, and do not want it.' In 1755, the degree of Master of Arts was conferred on him by the University of Oxford. After which, in May, his Dictionary came out. From the just value of this great and useful work, we are neither competent nor willing to detract. Considered as the work of one individual, it is a monument of Herculean strength; but when Johnson's lexicographical success is compared with that of the forty French academicians, and even preferred to it, the parallel can only be regarded as an illusion of national prejudice. For promoting works of poetry and imagination in a language, dictionaries are not the best receipts. The close definition of words deprives them of that halo of indistinct associations which delights the fancy—it prunes and trims the vegetation of language beyond the natural wildness of poetry; but for prose composition— for logical eloquence and for science, dictionaries and close definitions are not only important, but essential. The language of France has owed much more to this species of pruning, for it cannot be called cultivation, than our own; and evidently has owed much more than our own to its Dictionary. Its prose is superior to our own—its poetry incomparably inferior. Without regretting that we have no academy like that of our neighbours, we ought, in justice, to acknowledge, that Johnson has not given, perhaps, the fourth part of the distinctness and definition to our tongue that the French academicians have bestowed upon theirs. Johnson had great reading, and still more sagacity; but he was a bad etymologist, and very little acquainted with philological niceties.

In a pecuniary light, he derived very little benefit from the publication of his Dictionary; for, when it was finished, he had been paid more than the stipulated sum. He was, therefore, still entirely dependent on the exertions of the day for his support; and, it is melancholy to find, that a writer, esteemed an honour to his country, was, in the subsequent year, (1756,) in his 45th year, under an arrest for five pounds eighteen shillings. It is no wonder that his constitutional melancholy should at this time have exerted a peculiar sway over his mind.

About this period he was offered a living of considerable value in Lincolnshire, if he were inclined to enter into holy orders. It was a rectory in the gift of Mr. Langton, the father of one of his most intimate friends; but he did not accept of it, partly, says Mr. Boswell, I believe, from a conscientious motive, being persuaded that his temper and habits rendered him unfit for that assiduous and familiar instruction of the vulgar and ignorant, which he held to be an essential duty in a clergyman, and partly, because his love of a London life was so strong, that he would have thought himself an exile in any other place, particularly if residing in the country. In the same year, 1756, he endeavoured to superintend a monthly publication, entitled, the Literary Magazine, or Universal Register. To this he contributed a great many articles, enumerated by Mr. Boswell, and several reviews of new books. The most celebrated of his reviews, and one of his most finished compositions, both in point of style, argument, and wit, was that of Soame Jenyns's 'Free Inquiry into the Nature and Origin of Evil.' This attracted so much attention, that the bookseller was encouraged to publish it separately, and two editions were rapidly sold. He wrote also, in 1756, some essays in the Universal Visitor, another magazine, which lasted only a year. His proposal for an edition of Shakespeare was again revived, but it did not go to press for many years after.

In April 1758, he began a new periodical paper, entitled, the Idler, which came out every Saturday, in a weekly newspaper, "The Universal Chronicle, or Weekly Gazette," published by Newbery. These issues were continued till the April of 1760, amounting in number to one hundred and three, twelve of which were contributed by his friends, Mr. T. Marton, Mr. Langton, and Sir Joshua Reynolds. Though evidently the work of the same mind that produced the Rambler; yet as his biographer justly remarks, "it has less body, and more spirit." Many of these essays were written as hastily as an ordinary letter. Mr. Langton remembers John- son, when on a visit at Oxford, asking him one evening how long it was till the post went out; and, on being told about half an hour, then, he exclaimed, we shall do very well. He upon this instantly sat down and finished an Idler. Mr. Langton having signified a wish to read it: "Sir," said he, "you shall not do more than I have done myself." He then folded it up, and sent it off. No. 41 of the Idler alludes to the death of his mother, which took place in 1759. He had ever been a dutiful son, and had contributed to her support, often when he knew not where to recruit his finances. On the event of her death, he wrote his Rasselas, Prince of Abyssinia, that he might be enabled to raise a sum sufficient to defray the expenses of her funeral, and pay some little debts she had left. He told Sir Joshua Reynolds, that he composed it in the evenings of one week—sent it to the press in portions after it was written—and never read it again, till at the distance of several years. None of his writings have been so extensively diffused over Europe; for it has been translated
into most, if not into all the languages of modern Europe. Such, at this period, was the state of his finances, that he was obliged to break up house-keeping, and retire to chambers, where he lived, says his biographer, Mr. Murphy, in poverty, total idleness, and the pride of literature. From this unhappy state, he was at length rescued by the grant of a pension of £300 a year from his Majesty, in 1762, during the ministry of Lord Bute. When the liberal offer was made, a short struggle of repugnance, to accept of a favour from the house of Hanover, and become that character—"a pensioner," on which he had bestowed a sarcastic definition in his Dictionary, was overcome by a sense of the substantial benefit conferred by it. From the dates of Johnson's political writings, it is pretty clear that his pension was meant as a literary reward, and not as a political hire. That it might afterwards have influenced him to favour the court by the influence of personal gratitude, is not impossible; but there is no reason to believe that it ever made him prostitute his opinions. These were innately Tory; and it is easy to conceive how his loyalty, after the last hopes of the Jacobites had expired, might revert with sincerity to the throne, which had become legitimized by possession.

In the same year that he received his pension, he accompanied Sir Joshua Reynolds in a visit which he paid to his native county, Devonshire; was much delighted with his jaunt, and declared that he had derived from it a great accession of new ideas. He was entertained at the seats of several noblemen and gentlemen in the West of England; but the greatest part of his time was passed at Plymouth, where, according to Mr. Boswell, the magnificence of the navy, the shipbuilding, and all its circumstances, afforded him a grand subject of contemplation. While at Plymouth, he saw many of its inhabitants, and was not sparing of his entertaining conversation. It was here that he made a frank confession, that ignorance, pure ignorance, was the cause of a wrong definition in his Dictionary of the word pastor, to the no small surprise of the lady who put the question to him.

He now took a house in Johnson's Court, Fleet Street, and allotted an apartment in it for Mrs. Williams.

A fondness for liberal and cultivated conversation, was one of Johnson's strongest propensities; and he had sought it, as we have before mentioned, in a club of literary men, soon after his settling in the metropolis. His advanced reputation and amended circumstances, now enabled him to indulge it in a higher style; and he became member of a weekly club in Gerard Street, composed of persons eminent for various talents, and occupying distinguished situations in society. He also acquired an additional source of enjoyment, both social and intellectual, by his introduction, in 1765, to the acquaintance of Mr. Thrale, an opulent brewer, whose lady possessed a lively mind, highly accomplished by an enlarged education. In their hospitable retreat at Streatham, Johnson was for a considerable time domesticated, receiving every attention that could flatter his pride, and accommodated with every convenience and gratification that wealth could bestow. His scattered spirits were recruited, and his habits of life were rendered more regular in this agreeable residence.

In the October of this year, he at length gave to the world his edition of Shakespeare. His biographer Boswell's eulogy of this edition we forbear to quote, as we cannot agree with it. Undoubtedly there is much of Johnson's manliness and periphrasis shewn, both in the notes and in the preface; but the latter is written with the judgment of one who had reflected on the opinions of others, rather than felt deep impressions of his own respecting Shakespeare; and there is little or no depth of knowledge in the literature of Shakespeare's age. The edition, upon the whole, disappointed expectation. Its most valuable part is the summary views of the respective plays. In 1766 he furnished the preface, and some of the notes, to the new edition of the Plays by Mrs. Anna Williams. This lady was still an inmate in his house, and was indeed absolute mistress. Although her temper was far from pleasant, she had gained an ascendancy over him which she often maintained with peevishness; but he forgot her fretfulness in her distresses. His house was filled with other dependants besides Mrs. Williams, whose perverse temper frequently drove him out of it; yet nothing that he suffered from them could induce him to relieve himself at their expence. His noble expression was, "If I dismiss them, who will receive them?" In 1767, he had the honour to be admitted to a personal interview with his Majesty in the library of the Queen's palace. Of the conversation which passed, Mr. Boswell has given a very interesting and authentic account. On the inauguration of the Royal Academy of Arts, Johnson was appointed Professor in Ancient Literature, and probably at one time had some design of delivering a course of lectures; but, if he ever had the intention, he never fulfilled it. In 1770 he published a political pamphlet, entitled The False Alarm, intended to justify the conduct of ministry, and their majority in the House of Commons, for having virtually assumed it as an axiom, that the expulsion of a member of parliament was equivalent to exclusion, and thus having declared Colonel Lutterel to be duly elected for the county of Middlesex, notwithstanding Mr. Wilkes had a great majority of votes. This being justly considered as a great violation of the right of election, an alarm for the constitution extended itself all over the kingdom. To prove this alarm to be false, was the purpose of Johnson's pamphlet; but even his great powers were inadequate to cope with constitutional truth and reason, and his arguments failed of effect. The House of Commons were ultimately obliged to retrace their steps, and to expunge the offensive resolution from their journals. That the House of Commons might have expelled Mr. Wilkes repeatedly, and as often as he should be re-chosen, was not denied; but incapacity cannot be pronounced but by an act of the whole legislature. It was wonderful to see how a prejudice in favour of government in general, and an aversion to popular clamour, could blind and contract such an understanding as Johnson's in this particular case. That it embalmed to infuse a narcotic indifference as to public concerns into the minds of the people, and that it broke sometimes into an extreme censures of contemptuous abuse, is acknowledged even by his most partial biographer.

On the subject of Johnson's political opinions, it would be unjust to the small degree of liberality that is to be found in them, to omit the notice of his good wishes in favour of Catholic emancipation. Without inquiring too strictly how far his Toryism might have given him this bias as much as his sense of justice, it should be recorded to his honour, that his views on this subject were humane and liberal, and anticipated those which are gradually gaining ground against the receding prejudices of modern barbarism. He had great compassion, says Mr. Boswell, for the miseries and distresses of the Irish nation, particularly the Papists, and severely reproved the barbarous debilitating policy
of the British government, which he said was the most
detestable mode of persecution. To a gentleman who
hinted that such policy might be necessary to support
the authority of the English government, he replied by
saying, "Let the authority of the English government
perish, rather than be maintained by infamy. Better
would be to restrain the turbulence of the natives by
the authority of the sword, and to make them amenable
to law and justice by an effectual and vigorous poli-
tice, than, by an unrelenting persecution, to beggar and
starve them."

In 1771, he published another political pamphlet,
titled, Thoughts on the late Transactions respecting
Falkland's Islands, in which, upon materials furnished
to him by ministry, and upon general topics, expanded
in his rich style, he successfully endeavoured to per-
suade the nation that it was wise and laudable to suf-
fer the question of right to remain undecided, rather
than involve our country in another war. It has been
suggested by some, that he rated the importance of
these islands to Great Britain too low. However this
may be, to bring home the calamities of war, and the
eloquent description of its miseries, cannot be
over-praised.

Mr. Strahan the printer, who was himself a member of
Parliament, and who loved much to be employed in
political negotiation, thought he should do eminent ser-
vice both to government and to Johnson, if he could
be the means of his getting a seat in the House of Com-
mons. With this view he wrote a strong recommen-
dation of our author to one of the secretaries of the
Treasury; but, for reasons that are not well known,
the ministry did not take up his suggestion. It was
much agitated among his friends and admirers, wheth-
er, if he had obtained a seat in Parliament, he would
have distinguished himself in debate. Had he entered
the house at an early period of life, there can hardly be
a doubt that his knowledge and eloquence would have
commanded in the legislature a similar esteem to that
which they possessed in literature, but his own ac-
knowledgment that he had tried several times to speak
in the Society of Arts and Sciences, but that all his
flowers of oratory forsook him, render it probable that
he was too far advanced in age to commence the prac-
tice of public oratory. Eminence in parliamentary elo-
quence, in the ablest individuals, has been almost in all
instances gradual, and the result of training and ex-
perience.

His pamphlet, entitled the Patriot, in 1774, was com-
posed on the eve of a general election, in order to in-
dispose the people against the oppositionists; but the
strongest display of his political bigotry, was reserved
for his production, entitled, Taxation no Tyranny, which
was written as an answer to the declaration of the Ame-
rican congress, relative to the claims of Great Britain.
Long before this time he had indulged most unfavour-
able sentiments of our fellow subjects in America.
"They are a race of convicts," he said to Dr. John
Campbell, "and ought to have been thankful for any
thing we allow them short of hanging." In this
pamphlet on the right of Britain to tax America, there
is not even acuteness of sophistry, far less any thing
deserving the name of argument. Positive asser-
tion, sarcastical severity, and extravagant ridicule, which he
himself reprobated as a test, composed the rhapsody.
Ministers themselves thought it decent to retract some
of the absurdities which he put to press in defence of
their cause. They struck out, by his own confession,
one passage to the following effect: "That the colo-
nists could with no solidity argue from their not having
been taxed while in their infancy, that they should not
now be taxed; we do not put a calf into the plough,
we wait until he is an ox." He said, "they struck it
out either critically as too ludicrous, or politically as too
exaggerating; I care not which. It was their business!"

Dr. Johnson here speaks of his labours in a light that is
not far from venal.

A tour to the Western Islands of Scotland in 1773,
in which he was accompanied by Mr. Boswell, forms a
remarkable and entertaining incident in his life. His
stay in Scotland was from the 18th of August, in which
he arrived, till the 22d of November, when he set out
on his return to London. He came by way of Ber-
wick-upon-Tweed to Edinburgh, where he remained
a few days, and then went by St. Andrew's, Aberdeen,
Inverness, and Fort Augustus, to the Hebrides, the
principal object of his tour. He visited the isles of
Sky, Raasay, Coll,-Mull, InchKenneth, and Icolmillk.
He then travelled through Ayrshire by Inverary, and
from thence by Lochlomond and Dumbarston to Glas-
gow, then by London to Auchinleck, in Ayrshire, the
seat of Dr. Johnson's family, and by Hamilton back to Edin-
burgh, where he again spent some time. He then saw
the four universities of Scotland, its three principal ci-
ties, and as much of the Highland and insular life as
was sufficient for his philosophical contemplation.

Among his prejudices, a strong antipathy to the na-
tives of Scotland in general, had long been conspicu-
ous, and this journey exhibited many instances of his
contempt for their learning and abhorrence of their re-
ligion. When he published, however, the account of
his tour, two years afterwards, more candour and im-
partiality was found in it than had been expected; and
to the praise which is justly due to the elegance and
vivacity of his descriptions, it may be added, that the
Scotch were indebted to him, in some instances, for his
reprehension of customs and peculiarities from which
they have since departed. Prejudiced as he was, he
often made a fair war upon Scottish prejudices; and
though a slavon, he made some just remarks on the
sloth and discomforts that retard civilization. On one
subject he gave more offence to the national feelings
than truth and candour will permit us to sympathize
with. Our Celtic scholars have never proved the au-
thenticity of the poems ascribed to Ossian, and John-
son studly denied them to be authentic. If the advo-
cates for the authenticity of the Gaelic poems had con-
fined their pretensions to a few fragments, or to any
moderate ideas of their antiquity, the cause might have
admitted of a dispute; but when they supported Mac-
pherson's imaginary date of the third century, and the
existence of an entire epic poem, the sarcasms of John-
son's incredulity had their full force.

In the month of March 1775, he was gratified by the
title of Doctor of Laws conferred on him by the univer-
sity of Oxford, at the solicitation of Lord North.
In September, he visited France, for the first time, with
Mr. and Mrs. Thrale, and Mr. Baret. His journey
did not occupy more than two months. Foote, who
happened to be at Paris at the same time, said, that the
French were perfectly astonished at his figure and
manner, and at his dress, which was exactly the same
with what he was accustomed to in London,—his brown
clothes, black stockings, and plain shirt. Of the oc-
currences of this tour it is probable that he kept a
journal, though unfortunately he never perfected it,
from want of leisure or inclination. In the preceding
year he had also made a journey into Wales; but
Wales, he observed, is so little different from England,
that it offers nothing to the speculation of the traveller.
In 1770, he wrote nothing for the public. In that year he removed from Johnson’s Court to a larger house in Bolt Court, Fleet Street, with a garden, which he took delight in watering. A room on the ground floor was surrendered to Miss Williams, and the whole of the two pairs of stairs’ floors was made a repository for his books, consisting of about 5000 volumes. Here, in the interval of his residence at Streatham, he sat every morning receiving visits, and sometimes gave no inelegant dinners. Chemistry afforded him some amusement, and he had an apparatus for the study of it in his house. He had also a laboratory at Streatham, and diverted himself with drawing essences and colouring liquors for Mrs. Thrale. His last literary undertaking was in consequence of a request from the London booksellers, who had engaged in an edition of the works of the principal English poets, and wished to prefix to each a biographical and critical preface from his hand. Dr. Johnson executed this task with all the spirit and vigour of his best days. The publication of his Lives of the Poets began in 1779, and was completed in 1781. In a separate form, they compose four volumes octavo, and have made a valuable addition to English biography and criticism. The style of this performance is comparatively free from the stiffness and turgidity of his earlier compositions.

This was the last of Johnson’s literary labours; and, though completed when he was in his seventy-first year, shews, that his faculties were in as vigorous a state as ever. In the year 1781, he lost his valuable friend Thrale. Dr. Johnson’s friends were in hopes that Mr. Thrale might have made a liberal provision for him for his life; which as he (Mr. Thrale) left no son, and a very large fortune, it would have been highly to his honour to have done; but he bequeathed him only £200, which was the legacy left to each of his executors. With Thrale, many of the comforts of Johnson’s life might be said to expire. In the course of 1782 he complains, that he passed the summer at Streatham, but there was no Thrale. His visits to that place became less and less frequent, and, in the following year, entirely ceased. He kept up, however, a friendly correspondence with the widow of his friend, till she informed him of her intention to marry Mr. Piozzi, an Italian music-master. Johnson, as the executor of her husband, thought himself bound, in duty to the memory of Thrale, and the welfare of his children, to remonstrate with her on the intended step. Mrs. Piozzi’s answer contained an indignant vindication of her conduct and of her fame, and had a final adieu to her adviser, until he should have altered his opinion of the man of her choice. Of the charms of Dr. Johnson’s friendship the lady thus candidly expresses herself in her Autobiography: "Veneration for his virtue, reverence for his talents, delight in his conversation, and habitual endurance of a joke my husband first put upon me, made me go on so long with Mr. Johnson; but the perpetual confinement I will own to have been terrifying in the first years of our friendship, and irksome in the last, nor would I pretend to support it without help when my coadjutor was no more."

Thus excluded from the most agreeable dwelling in which he had ever been domesticated, he was compelled to return to his own house, to spend cheerless hours among the objects of his bounty, when increasing age and infirmities had made his company more obnoxious than before; and the society of which he had recently been deprived, rendered him comparatively less patient to endure it. From this time the narrative of his life is little more than a recital of the pangs of melancholy and disease, and of numberless excursions taken to calm his anxiety, and soothe his apprehensions of the terrors of death, by flying; as it were, from himself. His health began to decline more visibly from the month of June 1783, when he had a paralytic stroke; and although he recovered so far as to be able to take another journey to Litchfield and Oxford towards the close of the year, symptoms of a dropsy indicated the probability of his dissolution not being remote. Some relief, however, having been administered, he rejoined the society of his friends; and, with a mind still curious, intelligent, and active, renewed his attention to the concerns of literature, and tried his faculties by Latin translations from the Greek poets. During his absence, his friends endeavoured to procure some addition to his pension, that he might be enabled to try the genial effects of a warmer climate in the south of Europe. Application was accordingly made to the Lord Chancellor Thurlow, who applied to the Treasury for this purpose, but without success. His lordship, however, evinced his regard for his author, by offering to advance the sum of £ 500 for this object; an offer which Johnson declined, with the most dignified expressions of gratitude. Dr. Brocklesby also made a similar offer; nor were there wanting others who would have liberally supplied him for his continental tour. But these offers were not accepted, and his strength was becoming unequal to the effort of a journey. The dropsy and asthma were making hasty approaches. No man seems ever to have had the instinctive horror at the prospect of dissolution more strongly impressed on his mind than Johnson. Un fortunately for himself, he had a smattering of medical science, and imagining that the drenchical collection of water which oppressed him might be driven off by means of fomentations in the calves of his legs, he said to the surgeon who was making slight scarifications in his swollen legs, "deeper, deeper. I want length of life, and you are afraid of giving me pain, which I do not value;" and he afterwards, with his own hand, had punctures made for this purpose. Devotion, however, is said at last to have come to the support and pacification of his mind. He died on the 15th of December, in the seventy-fifth year of his age. His remains, attended by a respectable concourse of friends, were interred in Westminster Abbey, and a monumental statue has been since placed to his memory in St. Paul’s Cathedral. He left his property, a few legacies excepted, to a faithful black servant, who had long lived with him. A short time before his dissolution he had burnt large masses of paper, and, among others, two large quarto volumes, containing a full and particular account of his life. The loss of which might be a subject of regret, if the biographical accounts were not the most authentic. Johnson was at his death, and had been for some time before it, the most conspicuous character in English literature. He had less of the pure quality of genius than Goldsmith, but he had more energy in the expression of his prose style, and a more imposing air of consequence in giving weight to his opinions. He was not so truly eloquent as Burke, but he devoted himself more to literature. He was less learned than Warburton, but more popular from his choice of subjects, and superior to that scholar in richness of fancy. There was no contemporary prose writer whose style was more poetical: there was no poet who combined with the talent for poetry a command of prose so valuable and strong; yet his poetry is marked by precision of thought, and not by exquisite feeling, and his prose is far from being chaste or idiomatic. It abounds with
JOHNSON.

Johnson, Samuel.

the formality of antithesis, with Latinisms, with too much abstraction of terms, with a rotundity of words that is often more sonorous than instructive, and with a pump of metaphor that is frequently applied to trivial ideas. Still there is a breadth and magnificence in his style, considered as the drapery of his thoughts, that makes the richness of its tissue alone for the stiffness of its folds. And if his colours of language be gorgeous, his ideas are for the most part sufficiently vigorous to stand exposure in the strongest light.

As a critic, where his political or accidental prejudices did not happen to interfere, he could seize more vigorously, than almost any other mind, upon the main outlines of merits and defects in poetry, and illustrate them with a force and felicity entirely his own. But we believe it will be generally granted, that though he fully possessed the great outlines of critical discernment, he had not that finer tact of sensitivity which directs to the more latent and exquisite beauties of poetry. Garrick complained, and we believe justly, that he was wholly dead to the finest impressions of tragedy; yet no one could give, in general terms, a more just description of the merits which tragedy should possess. His critical sensibility was sagacious, not sensitive. Those who blame him for not going deeper among our ancient poets, in his edition of them, forget that the study of our elder poets was but then begun. Of the poets whom he criticised, he made, upon the whole, a pretty fair estimate. It is the rage of modern taste to exaggerate the merits of all our old minor poets; Johnson's work will probably serve, in a future age, to counteract this overweening opinion. Indeed, at this moment there is no critical authority to which we should resort more willingly, than to his, against the tasteless depreciation of Pope, which has of late been so ominously current. The history of his life cannot be perused without many recollections of personal esteem. The traits of his charity and benevolence to the unfortunate are very numerous. He was a dutiful son and a kind master; and the spectacle of his early career, that of a friendless scholar, supporting himself by the toils of literature, bursting forth upon the world as a man of genius, through the clouds of poverty, depression, and hypochondria, and maintaining all along a virtuous pride and independence of character; this is an object of interesting and even of elevated contemplation. It may soften our animadversion, though it cannot wholly blind us to his faults as a philosopher and a man. In neither of these views, whether we consider him as an individual member of society, or a teacher of the truths that publicly interest society, can he be held up as an object altogether entitled to be loved, or fit to imitated. He seems neither to have felt nor practised one of the first duties of a member of society—that of social and civilized deportment. The history of his conversations, as related by Mr. Boswell, gives us the picture of a strong and amusing, but of a coarse and insolent mind. Whatever praise may be due to his strictly private and domestic virtues, he often brought no better feelings into promiscuous society, than those of spleen, egotism, and domineering pride. We are told by his biographers only of his victories in the warfare of conversation; but private tradition has preserved many anecdotes of his insolence being properly chastised, and often in the most humiliating manner, by individuals who were his inferiors in general knowledge. It would have been well if these had been recorded with equal assiduity as his triumphs; for his example was calculated to injure the tone of general manners; and it is certain that there were at one time many asp more of his manner in conversation, as well as in writing. But, happily, the prevailing manners of polite life are now such, that the dogmatic manner of a Johnson would not at this moment be tolerated.

He was an advocate of arbitrary power in polities, though it is but justice to mention with what particular qualifications. He abhorred the existence of absolute slavery, and used to express his detestation of that remaining blot upon our national character, the slavery of negroes in our colonies. He wished well to Roman Catholic emancipation; and even after the alarm of the memorable riots in London, rejoiced that the acquittal of Lord George Gordon had not sanctioned the doctrine of executing a man for constructive treason. So far his sense of rectitude prevailed, in particular cases, over his general tenacity of bigotry and despotic sentiments. But the main current of his opinions ran in the latter channel. We need not trouble the reader with quotations; for the most who have perused his life, must remember many traits of his superstition and intolerance. He bowed to a bishop as to a being of a superior nature. He abused, in the most rancorous terms, a young woman who had been guilty of quitting the established church, and joining the society of Quakers, declaring that she had no right to think for herself on the subject. He spoke of Rousseau as one whom he would have rejoiced to punish as a felon. We are not disciples of Rousseau; but we have no hesitation in declaring our opinion, that some of Dr. Johnson's tenets were not less noxious than those of the philosopher of Geneva. In point of immediate and obvious evil tendency, nothing that Rousseau ever wrote was so pernicious as our author's pamphlet on the subject of our dispute with America. It may not be easy to ascertain how much influence that production exercised in biasing the public mind towards hostilities; but he lent his influence, such as it was, to sanction unjust pretensions, and to promote the exasperation and sufferings of millions of his species.

The tendency of his abstract sentiments in favour of arbitrary power, was, perhaps, not very mischievous. It is chiefly in confined and particular questions that the sophistry of an illiberal writer can do much harm. Taken in a general view, an animated author counteracts all the evil impressions which he can make against the cause of liberty, by the spirit of discussion which he awakens, and by the attention and contradiction which he provokes. Johnson defended principles with his pen, which, in the long run, can never be supported but by the sword.

Nevertheless, when we assign to departed individuals their respective rank in the scale of benefactors to their species, we cannot forget the question, whether they have lent the strength of their talents to promote the progress of moral civilization, or to retard the emancipation of the human mind from bigotry and servility. Had the leading spirits of our literature been all like Dr. Johnson, we might have been at this day burning witches, and believing in the second sight. With what contrasted feelings do we rise from perusing the life and writings of that Milton, whom our author has pourtrayed with the heavy hand of malignant hatred! Milton left his contemporaries behind him, in his high moral and political views, and bequeathed to the world a capital in the island of Sky congenial with his own opinions. (a)
JOINERY.*

Joinery is that branch of civil architecture, which treats of the art of framing and joining wood together for the internal and external finishing of houses.

The smoothing of wood, by cutting the superfluous parts away in thin flat slices, is called planing; and the tools used for this purpose are called planes, whether they are employed in reducing the surface to a plane, or to a convex, a concave, or an undulated form.

The wood is called stuff, and is previously formed into rectangular prisms by the saw. Those prisms are denominated boards, battens, planks, &c. according to their dimensions in breadth and thickness. So that in this article, whenever a piece of wood is spoken of, it is understood to be bounded by six planes, and to have all its angles right angles.

The arrises are the lines of concourse formed by every two planes, and are therefore eight in number.

Deals are of two kinds, white and yellow; the white is employed for panelling, and the yellow for the framing. But of late, instead of white deal, American wood has been brought into use, and employed both in framing and panelling. It is soft, very free from knots, and easily wrought; but is more liable to warp than white deal.

Of Mouldings.

As mouldings have already been defined under Civil Architecture, we shall here only point out those which are commonly used in joinery.

Wood is generally much thinner than the dimension of its breadth, reckoning the breadth and thickness on the sides of the rectangular section made by cutting it perpendicular to the fibres, the length being understood to be parallel to the fibres. The faces are the two broad planes that run in the direction of the fibres; and the edges are the two narrow planes which also run in the direction of the fibres. The ends are the two planes perpendicular to the fibres.

When the wood has been reduced to the rectangular shape by the square and plane, so that the sides may be planes, and the angles right angles, the next operation is to take away the right angles, and reduce the wood to mouldings, which is called sticking, and the moulding is said to be stuck.

When the edge of a piece of wood is reduced to a cylindrical form, it is said to be rounded, which is the simplest species of moulded work.

When a part of the arris is reduced to a semicylinder, so that the surface of the cylindrical part may be flush, both with the face and edge of the wood, and that a groove or sinking may be made in the face only, the cylindrical part is called a bead, and the sinking a quirk, so that the moulding is called a quirked bead.

When a quirk is also formed in the narrow plane, or edge, so as to make the rounded part at the angle three-fourths of a cylinder, the moulding obtains the name of bead and double quirk.

When there are two semicylindrical mouldings, rising both from a plane parallel to the face; and when one comes close to the edge of the piece, and the other has a quirk on the farther side and its surface flush with the face of the wood, the combinations of these mouldings are termed a double bead, or double bead and quirk. In this combination, the bead which is next to the edge of the stuff is much less than the other.

Mouldings are generally separated from one another, and frequently terminated by two narrow planes, at right angles to each other, called fillets, which shew two sides of a rectangular prism.

Mouldings, as well as fillets, are called members.

When a semicylindrical moulding, which rises from a plane parallel to the face, is terminated on the edge by a fillet, the two members thus combined are called a torus.

If there be two semicylindrical mouldings springing from a plane parallel to the face, terminated on the edge by a fillet, this combination of members is called a double torus.

A repetition of equal semicylindrical mouldings, springing from a plane or cylindrical surface, is called reeds.

The cima recta, and cima reversa, are called in joinery ogee. The former is called ogee, and the latter ogee reverse.

Ogee has already been defined in our article Civil Architecture.

A quarter round is the fourth part of a cylindrical surface, but has no quirk on either side.

Mouldings for Framing.

In framed work, as doors, shutters, wainscoting, &c. Mouldings for framing, the edges of the framing is generally reduced at the angles to mouldings. The mouldings for this purpose are the ovolo, or the ogee, with or without a bead next to the panel; but when the ovolo is employed, a bead or a fillet becomes necessary. The ogee is either common or quirked, with a bead at the bottom.

When the margins of the framing terminate on the edges next to the panel, with one or more mouldings, which both advance before, and retire from the face of the framing to the panelling. The mouldings thus introduced are called projection mouldings.

The panelling of framed work is generally sunk within the face of the framing; sometimes, however, for outside work, it is made flush. In the best flush work, the panels are surrounded with a bead, formed on the edge of the framing, and the work is called bead and flush. In the more common kind of flush framing, the bead is run on the two edges of the panel in the direction of the fibres, and is called bead and butt.

Fig. 1. Plate CCCXXXIII. Fillets.
Fig. 2. Edge rounded. This simple moulding is also sometimes called a bead; but not unless it is fixed to one side of a rectangular piece of wood, and the rounded part made flush with the other side.

Scribing and Mitreing.

When two bodies are so fitted together that their surfaces intersect or meet each other, they are in general said to mitre or scribe.

Two bodies are said to mitre together in a plane passing through the common intersection of their surfaces.

One body is said to scribe upon another, when the two surfaces intersect each other, and when so much of the 'one body is cut off to make way for the other body entire.

In finishing, whether the bodies are mitred or scribed, the external appearance is the same.

As the theory of the intersection of geometrical bodies with one another has been omitted in the article Carpentry, where it is absolutely necessary in the practice of groins and arches, in order to make correct work; and as it is also essential in joinery, in mitreing, and scribing, we shall make no apology for inserting it in the present article.

The bodies which we shall suppose to be joined together are prisms, cones, and conoids.

Prisms include all solids which may be cut into equal and similar sections by parallel planes, and which may also be cut by parallel planes in some other direction into parallelograms of the same length; and consequently by this definition, not only triangular, rectangular, and polygonal prisms are included, but also cylinders, cyhndroids, and such as may have parallel sections, equal and similar parabolas, or equal and similar hyperbolas.

Parabolic and hyperbolic prisms are here supposed to be generated in the following manner. Imagine the plane of the figure to be, with its apex, along a straight line perpendicular thereto, while its axis or double ordinate to the axis may describe a plane.

In order to prevent repetitions, let it be understood, that when two prisms intersect each other, that they intersect at right angles.

The method of ascertaining the construction of the meeting of the surfaces of two different bodies, is to suppose the position of the one body given in respect to the other, and the position of both in respect to a given plane, and the projection of the intersection of the two surfaces to be made on that plane.

For the purpose of projection, let us suppose that besides the plane on which the projection is made, there are two others at right angles, forming, with the plane of projection, an internal solid angle.

To render the practice of this easy, we shall suppose that when the intersection of two prisms is required, the ends are placed at right angles to the plane of projection, and that the double ordinates of their generating figures are parallel thereto.

Let us suppose, in the case of two prisms joining, that the planes generated by the axis of the generating figure of each prism, are the plane whose distances are respectively $x$ and $y$.

Or, in the case of a prism joining with a conoid, that the plane described by the axis of the generating figure of the prism, and the plane passing through the axis or centre of the conoid at right angles therewith, and also to the plane of projection, are the two planes whose distances are respectively $x$ and $y$.

Ex. 1. Suppose two parabolic prisms to intersect each other, so that the apex line of one prism, and the rectangle opposite the apex line of the other, may be in the plane of projection.

Draw $BP$ parallel to $CD$; make $AC = a$, $CD = b$, $AB = z$, and $BP = y$. Draw $BP'$ parallel to $CD'$; make $CA' = a$, $CD' = c$, $CB' = z$, and $BP' = x$; therefore $BA'$ will be $a - z$.

Then, by the property of the parabola,

in the section $APDC$, $a:z::b':y^2$; therefore $z = \frac{b' a y^2}{b}$.

and in the section $CD'PA'$, $a::x::e':c^2$; therefore $x = \frac{e' a c^2}{c^2}$.

Consequently, $\frac{a y^2}{b'} = a - \frac{a c^2}{c^2}$; whence we infer, that the curve $FGHI$, which is the projection of the two prismatic surfaces is an ellipse.

If $b = c$, the projection will be a circle.

Ex. 2. Suppose the generating figures of both prisms to be parabolas, as before; and that the rectangle described by the double ordinate of each is on the plane of projection, to find the projection of the intersection of their surfaces.

Let $APDC$, Fig. 21. Plate CCCXXXIII. be the generating figure of the one prism, and $A'P'D'C'$ that of the other. Make $CA = a$, $CB = z$, $CD = b$, and $BP = y$; also $C'A' = c$, $C'B' = z$, $C'D' = d$, and $B'P' = x$; therefore $BA = a - z$, and $BA' = c - x$.

From the property of the parabola we have from the figure $APDC$, $a::z::b':x^2$; whence $z = \frac{a x^2}{b'}$, also from the figure $A'P'D'C'$, $c::z::d':y^2$; whence $z = \frac{c y^2}{d'}$; therefore $a = \frac{b}{b'}\frac{a x^2}{d'} = \frac{c y}{d'}$. 

End of the section of geometrical bodies.
therefore \( y^2 = \frac{d}{c} (c - a) + \frac{a}{b} x^2 \); whence we infer

that the curve is a hyperbola; and if \( a \) and \( c \) become
equal, we should then have \( y^2 = \frac{d}{b} x^2 \), or \( y = \frac{d}{b} x \),
and consequently, in this case, the projection of the in-
tersection of the two surfaces would be straight lines,
and would form the figure of a groin; and if \( b \) and \( d \) were
equal, we should have \( y^2 = \frac{d}{c} (c - a) + \frac{a}{c} x^2 \), which
is a case that would more frequently occur in practice.

Example 3.

Ex. 8. Suppose the generating figure of the one prism
to be a semi-ellipse, of which the greater axis is the base,
and the generating figure of the other to be a semi-
circle; and that the rectangle described by the greater
axis of the former, and the rectangle described by
the diameter of the latter, are in the plane of projection.

Let \( A'P'D'C \) be half of the generating figure of the elliptic-prism,
semi-cylindrical, and \( A'P'D'C' \) be half of the generating figure of the semi-
cylinder. Make \( C A = a \), \( C B = z \), \( C D = b \), and \( B'P' = y \);
also \( CA' = c \), \( C'B' = z \), \( C'D' = d \), and \( B'P = y \).

Then, from the property of the ellipse, in the figure \( A'P'D'C \), we have \( a^2 x^2 + b^2 y^2 = (a + z) (a - z) : x^2 \); whence
\( a^2 x^2 = b^2 (a^2 - z^2) \). Therefore \( z^2 = a^2 - \frac{b^2}{a^2} x^2 \).

Again, from the property of the circle in the figure \( A'P'D'C' \), we have \( y^2 = (d + z) (d - z) : y^2 \); whence \( y^2 = d^2 - z^2 \); therefore \( y^2 = a^2 - \frac{b^2}{a^2} x^2 \).

Whence we infer that
the curve is a hyperbola.

This example is exceedingly useful in groined arches.

Let \( y = 0 \), then will \( z = d^2 - a^2 + \frac{b^2}{a^2} x^2 \), whence \( x = \frac{b}{a} \sqrt{(a^2 - d^2)} \), which is half of the greater axis of the
curve. Suppose \( y \) infinite, then will \( x = \frac{b}{a} \sqrt{a^2 - d^2} \), or
\( y = \frac{a}{d} x \), therefore \( a : b : : y : x \), that is \( G : F \) : \( E : : x : y \);
whence \( GE \) is an asymptote to the curve. If \( a = b \), as
is generally the case, we shall have \( y^2 = d^2 - a^2 + x^2 \);
and in this case, if \( y = a \), we shall have \( x^2 = a^2 - d^2 = (a + d) (a - d) \); therefore this particular value of \( x \) will be a mean proportional between the sum and
difference of the two radii.

Of the various Forms of Joints for Doors and Shutters,
and of the Methods of Hinging them together.

The forms of joints for folding and hinging is essent-
ial to the beauty of the work. Such joints ought to
be so made, as to preserve the uniformity of the door
or shutter on both sides; and to exclude as much air
as possible from rushing through between the edges of
the two bodies to be hinged, and thereby rendering
the apartments cool in winter.

In the joints of doors which are to be hinged to-
gether, both angles of one of the bodies are usually bea-
sed, in order to conceal the open space which would
be seen from every point of view; and to preserve the
regularity of the work, the hinges employed to couple
them together are made exactly to the size of the bead,
on the side on which the knuckle is to be placed; so
that, when they are hung, the knuckles of the hinges
and the wooden bead form one continued staff or cy-
linder.

Plate CCCXXXIV. Fig. 1. Nos. 1. and 2, is a section Plate
of part of the door style and part of the hanging style
CCCXXXIV. of the joint. In this, the centre of the bead on each Fig.
side is in the line of the straight part of the joint from
the opposite side. To form the joint exactly, let \( c \) be
the centre of the bead, \( A G \) part of the joint in a line with
the edge of the same, join \( A C \), and draw \( AB \) perpendicular
to \( AC \); the other part \( B H \) is perpendicular to \( EF \), the face of the door or hanging style. This joint
will be found sufficient for many purposes, and may be
hung with common hinges, and, being crooked, will
break the current of air.

Fig. 2. Nos. 1. and 2, is a plane joint, beaded alike on Fig. 2
both sides. Here, as the plane of the joint is a tangent
to the cylindrical surfaces of both beads, the margin will
be alike on both sides, and therefore affords no check
in preventing the cold air from rushing through the
aperture or seam into the apartment. Another inconve-
nience is, that the hinge which is to connect the two
bodies must not be made in the usual manner, but in the
form shown in No. 3, where the bodies are hinged
together.

Fig. 3. In Nos. 1. and 2, the plane of the joint from Fig. 3.
the one side is directed to the axis of the bead on the
other. This joint is upon the same principle as Fig. 1.
and therefore may also be hinged with common hinges,
as at No. 3, where the two parts are coupled together.
These forms of Figs. 1. and 3. are applicable to those
cases where a part of the margin is concealed on one
side of the door.

Fig. 4. In Nos. 1. and 2, the beads are of the same size Fig. 4.
on both sides, and are exactly opposite to each other,
and the joint is broken by indenting a part which termi-
nates by a plane directed to the axis of the two op-
opposite beads. This form is not only beautiful and
strong, but tends to make the apartment comfortable,
and the hinges only require to be of the common form.
No. 3. shews the two parts hinged together.

Fig. 5. In Nos. 1. and 2, the beads are placed alike on Fig. 5.
both sides, but not on the same piece as in Fig. 4; and
though the uniformity is preserved, the bead which
projects the whole of its thickness is weakened.

Fig. 6. Shews the method of hinging shutters and con-
celling the hinges. \( A \) is the inside bead of the sash frame, \( B \) the inside lining, \( C \) part of the style of the shutter.
To find the form of the joint, let \( a / \) be the face of the
shutter perpendicular to \( a r \), the face of the inside lin-
ing. Bisect the angle \( a r \) by the straight line \( a \); then,
taking any point \( c \) in the centre, draw \( d d \) perpen-
dicular to \( a c \), cutting \( a a \) at \( c \); and \( c \) is the centre
of the hinge. From \( c \) describe an arc \( a m \), which must
be hollowed out of the inside lining of the sash, from
the whole height of the shutter; and the internal right
angle must be cut out of the edge of the shutter to the
breadth of the hinge, in order to make way for the hinge
in the set of opening and shutting. Here the toils of
the hinges are shewn of different lengths, in order to
strengthen them.

Fig. 7. Is a joint with concealed hinges intended for a Fig. 7.
door; and here, as the door is sufficiently thick, the
ends of the hinges are of equal lengths, and are concea-
el in the thickness of the wood.

Fig. 8. Is the method of hinging shutters in the com-
mon way, where the hinge is let its whole thickness

209
Fig. 9. Shows the method of hanging a door with centres which are entirely concealed. Suppose $a$ that part of the side of the jamb which comes in contact with the edge of the door; bisect $a$ and $b$, and draw $bc$ perpendicular to $ad$; make $be$ equal to $ba$ or $bd$, and join $ac$ and $ed$. From $e$ describe an arc $ae$, which shows the part to be hollowed out of the jamb. The centres are fixed to the top or bottom of the door. The upper centre must be so constructed as to admit of being taken out of the socket, so that the door may be unhung, as may be required.

Fig. 10. Shows the method of hanging shutters in the usual way, where the centres of the knuckle of the hinge is placed exactly opposite to the perpendicular part of the rebate. The dotted lines shew the flap exactly as folded back.

Fig. 11. Shows how the hinge is to be placed when the axis of the knuckle cannot be placed opposite the joint. Thus, let $ab$ be the distance of the edge of the flap from the edge of the shutter; bisect $ab$ in $c$; then $c$ is the point opposite to which the centre of the hinge must be placed. This situation for the knuckle of the hinge becomes necessary, when the shutters are not square at the ends, or when the boxing-room is not sufficiently ample. The principle is to place the centre of the knuckle of the hinge at half the distance of the edge of the flap from the rebate on the edge of the shutter.

Fig. 12. Shows the two parts as hinged together.

Fig. 13. When a door has a cornice, or other projecting moulding, and when it is required to bring the doors in a situation, when open, parallel to its place when shut, the knuckle of the hinge must be made to project as far, or something more, than the cornice or capping moulding. This principle will be sufficiently evident by inspecting the figure. The dotted lines shew the situation of the door when folded back.

Fig. 14. Shows the form of a rule-joint, either for shutters or furniture that require to open no farther than a right-angle, and that are to be exposed at the external angle. Here the centre of the hinge must obviously be in the centre of the arc.

Fig. 15. Shows the same when turned to a right-angle.

Shutters are always within the apartments, wherever beauty is aimed at; those on the outside destroying the appearance of the front. They are divided into several vertical slips folding behind each other, for the convenience of concealing them within the thickness of the wall. Each slip or fold is framed and composed of several panels, either raised, or flat, surrounded with small mouldings contained within the thickness of the framing.

The case in which the shutters are enclosed, is called the boxing. The parts of the sash-frame in connection with the shutters, are the inside lining which forms one side of the boxing, and to which the front shutter is hung. The vertical piece of wood which adjoins the edges of the sashes and the inside lining, is called the pulley style. The vertical piece of wood which joins the pulley style on the outside, parallel to the inside lining, is called the outside lining. That side of the boxing which is parallel to the face of the shutter, is called the back of the boxing. The remaining third side of the boxing is either formed by the architrave which surrounds the aperture within the room, or, in very good houses, by a groined flush on one side with the plaster of the wall. The parts of the sash-frame which are parallel to the horizon, are the sill and top, which names bespeak the situation in which they are placed.

Inside beads are those slips of wood, rounded on the edges, which form one side of the race or groove for the sashes to run in. Parting beads are those slips of wood which separate the upper and lower sashes.

The method of making doors open exactly, so as to cut away the least quantity of wood, or to keep the narrow planes of the edges as nearly perpendicular to the face of the work as possible, depends upon the following principle.

Supposing a correct section to be drawn, then if the aperture be shut with a door to open in one breadth, draw a straight line from the centre of the hinge to the opposite angle of the plane; perpendicular to which, draw another straight line, and this perpendicular will give the splay of the jamb which comes in contact with the edge of the door which is to be fastened or locked there. If the aperture is closed with two doors, the principle is still the same, as it is only necessary to consider one of them to open at a time, while the edge of the other, which is bolted to the floor and soft, is considered as a jamb; then proceeding with the other half, which is thus left to turn on its hinges, as if it were a whole, in the same manner that we have now described.

Fig. 16. Shews the section of a door for a straight wall.

Fig. 17. Is the section of folding doors. Here it will be necessary to attend to the principle.

Fig. 18. Is the section of a door in one breadth in a Fig. 18. circular wall. Here the joints should tend to the axis of the cylinder.

Fig. 19. Is the section of a door in a cylindrical wall, Fig. 19. in two parts. In this the above method should be attended to.

Fig. 20. Is the section of a double door, to open to Fig. 20. the space on the concave side. Here, in particular, the above method of making the doors open to clear the jams should be attended to.

Fig. 21. Is the section of a single door, to open to Fig. 21. the concave side. Here the principle of making it open must also be attended to.

Raking Mouldings.

Raking mouldings depend upon the principle of a raking solid angle consisting of three plane angles, or what mouldings may be called a trihedral; and this may be considered either as a hollow or as a solid, according as it may be used externally or internally. The mouldings are supposed to be placed in two of the lines of concourse, and to meet each other in a plane passing through the other line of concourse.

The raking mouldings of a pediment are placed upon a solid trihedral, the horizontal moulding being disposed upon the obtuse angle, and the raking mouldings upon the top of the tympanum. In this case, the mitre of the mouldings is in the same plane with the line of concourse of the two sides of the building.

The three planes which terminate in a point in the inside of a rectangular room, may be considered as a hollow trihedral. Now, if these three planes which constitute the trihedral be at right-angles, no difficulty can occur in constructing the mouldings, as each cornice may have the same section, and as the direction of both cornices are perpendicular to the line of concourse of the two vertical sides of the room; but where the one cornice is perpendicular, and the other oblique, the case becomes the same as the preceding.
The principle is also applied to the bars of a bow window, of which the sides form a polygonal prism.

In this, the trihedral is considered as formed by the face of one of the vertical planes; a vertical plane bisecting the two adjoining faces and a horizontal plane.

Let us suppose the inclination of the two planes through which the plane of the mitre passes, and the other two angles of the trihedral to be given. The projection of each mitre, and the figure of the mitre, or the section of one of the mouldings and the mitre line, must also be given, and we shall have sufficient data in order to ascertain the section of the other moulding.

This construction becomes very easy, where the inclination of the two planes is a right-angle, and when the angle contained by the edges of the one plane is a right-angle, and that contained by the edges of the other an obtuse angle, as is the case with a pediment.

The plane of the two adjoining walls is generally a right-angle, and the angle contained by two of the edges of one of the planes is an obtuse angle, and that contained by the two edges of the other a right-angle.

This case affords a very easy construction; it being only necessary to lay down the side of the building on which the pediment or inclined cornice is to be made, with a projection of the mouldings at the lower end, without any plan whatever, provided that the mouldings have the same projection on both sides.

The same is also the case with regard to the two sides of a bow window, where the sides are vertical planes at any angles with each other.

Fig. 1. Plate CCCXXXV. Shows the elevation of a triangular pediment with a modillion cornice.

Fig. 2. Shows the elevation of an open pediment with the same cornice as Fig. 1. It is in such cases as these that raking mouldings occur.

Fig. 3. Shows the method of tracing a raking cima recta. The curve turned towards Fig. 2, is the return moulding in the open part of the pediment, Fig. 2. The curve next to the margin of the plate is the return moulding at the lower extremities of the pediments, Fig. 1 and 2. The middle curve is a section of the raking or inclined moulding itself.

Fig. 4. Shows also front of a modillion, with the raking moulding, which forms the cap. The upper extreme curve is a section of the level return at the top; the lower extreme curve is a section of the level return moulding at the bottom; and the curve shown in the middle is a section of the raking moulding itself. This is the same moulding as shown in the designs of Figs. 1 and 2.

Fig. 5. Shows the section of a raking cavetto, and that of the return moulding at the bottom.

Fig. 6. Shows the section of a raking ovolo, and the sections of the return mouldings at the top and bottom. As the principle of all these is the same, though the forms are different, we shall here describe the method of tracing these curves. Admitting the curve ABCDEF at the bottom to be given: draw lines Bb, Cc, Dd, Ee, Ff, parallel to Aa, or to the fillets of the moulding; Draw AF, BK, CL, DM, EN, FO perpendicular to FG, and draw any straight line KLMNO parallel to FG, place the distances K, KL, LM, MN, NO, upon any part of the fillet, and draw the straight lines i, a, b, c, d, e, f, and a b c d e f is the section of the raking moulding. In the same manner, by drawing any straight line k l m n o parallel to FG, and drawing i, a, b, c, d, e, f, perpendicular to FG, we shall obtain the curve b c d e f, and the lower side of the fillet a b for the section of the return moulding at the top, if any should be wanted.

Fig. 7. Section of a raking architrave and soffit for the return of a splayed window, which is sometimes both necessary and ornamental in thick walls. No. 1. is the architrave for the soffit, which we shall suppose to be given in order to obtain No. 2. Let DF represent a section of the plane of the face of the soffit, then to find any point in the curve, draw E e perpendicular to DF cutting C f, the face of the raking architrave, at f; make f e equal to FE, and e will be a point in the raking moulding of the splayed architrave. Other points will be found in the same manner, and when a sufficient number are obtained, the curve may be drawn through these points by the hand.

Fig. 8. Is another design finished with reeded mouldings; the method of tracing is the same, but this is more particularly explained in the next figure.

Fig. 9. Is the method of tracing the moulding of a raking architrave more particularly explained. The moulding chosen for this purpose is an ogee reverse. No. 1. is the given moulding. No. 2. the raking one, which is required to be found. AE, e E, are the edges of the mouldings, which are supposed to be in the plane of the finishing of the walls. EF and ef are the fillets which front each other. FG, f g, the sides of the quirks of the mouldings. KE, k k, the faces of the fillets. LR, l k, the returns of the same, and IQPQONG, and iq pq on g, ogee mouldings. Then to find any point in the curve, draw Lh parallel to AB, and suppose these mouldings to be of equal thickness, draw ae perpendicular to BC; make a e equal to AE; draw HM perpendicular to AE, cutting it at M; make a m equal to AM, and draw m h parallel to BC, h will be a point in the raking moulding as required. In the same manner, all the other points will be found and completed as before.

Fig. 10. Is a torus moulding for skirting stairs. The curve at the lower end shows the section that the moulding at the return makes in the passage below. The upper curve is a section of the moulding on the return at the landing. The middle curve is a section of the moulding placed in the staircase itself. This form of oblique curvatures would only take place in a straight flight of stairs, where the steps both begin and end in the passages.

Fig. 11. Shows the method of mitring skirting, where Fig. 11. the wall of a staircase is continued before the first step, and after the landing.

Fig. 12. Shows another method, by taking away the Fig. 18. angles. Thus take two equal distances AB and AC. Draw BD perpendicular to AB, and CD perpendicular to AC. Then with D as a centre, describe the arc BC, which is the curve required.

Fig. 13. Shows the method of finding the forms of Fig. 13. the bars of a bow window. The principle is the same as described in Fig. 9. No. 1. is a section of the given bar. No. 2. is a section of the raking bar in the mitre of an oblique angle. No. 3. section of the bar in a right angle.

**Formation of Bodies in Parts by joining them with Glue.**

Plate CCCXXXVI. Fig. 1. No. 1. Is a section of two boards glued edge to edge. No. 2. face of the same. Fig. 2. A section of two boards glued edge to edge, with a tongue inserted in a groove in each piece. By these means, a board may be made to any breadth, though the pieces which compose it be ever so narrow.

Fig. 3. Two boards fixed at right angles, the edge of the one being glued upon the side of the other. They Fig. 1—3. are strengthened by a block, which is fitted and glued to the interior sides.
Fig. 4. No. 1. A section of two boards at an oblique angle, mitred and glued together, with a block in the angle. No. 2. shows the inner sides of the boards thus fixed. By this method columns are glued up.

Fig. 5. No. 1. Section of an architrave. As the moulding is generally, if not always glued to the plate or board, the dotted line circumscribing the moulded part shows the section of the piece to be glued. No. 2. face of the architrave. No. 3. a section of the architrave before it is moulded. No. 4. a front of the same. No. 5. a section of the same to a reduced size, with the button and nail, shewing the manner in which the two parts are glued together. No. 6. shews the back of the architrave with the buttons. The black dots show the heads of the nails. The buttons are used, in order to bring the two surfaces which are glued together in contact, after the pieces have been set and held together, and are afterwards knocked off when the glue becomes dry, and then the moulding is stuck, as shewn by the section, No. 1. and elevation, No. 2.

Fig. 6. Shews the method of glueing up a solid niche in wood. No. 1. is the elevation. Here the work is constructed in the same manner as if it were stone or brick, except that the joints are all parallel to the plane of the base; for it is difficult to make a joint with curved surfaces, as would necessarily be the case if they all tended to the centre of the sphere. No. 2. and No. 3. show the bottom courses, where the vertical joints are made to break, and not to fall in the same planes.

This is distinctly seen in the elevation, No. 1.

Fig. 7. Shews the manner of glueing veneers together, so as to form a cylindrical surface. This is done by nailing brackets to a board, with their faces upwards, and their ends perpendicular, leaving a cavity sufficient for the veneers and wedges between the ends. In No. 1. the thin part in the form of an arc shows the veneers in the state of being glued, and the wedges are shewn upon the convex side. No. 2. is a section of the board and bracket. The veneers ought to be heated before a large fire, and the glue laid on the surfaces that are to come in contact as hot as possible, to prevent the glue from setting, observing to glue only a small portion at a time, and then wedge it up. When the glue is dry, the wedges must be slackened, and the veneers, which will then form one solid, taken out.

Fig. 8. Shews a very strong method of forming a concave surface, by laying the veneer upon a cylinder, and backing it with blocks in the form of bricks, which are glued to the convex side of the veneers, and to each other. The fibres of the blocks must be as nearly parallel as possible to the fibres of the veneers. No. 1. shows a section of the cylinder, veneer, and blocks. No. 2. shows the convex side of the blocks.

Fig. 9. Shews another method of glueing veneers together with cross pieces screwed to a cylinder, the veneers being placed between the cross pieces and the cylinder.

Fig. 10. Shews the method of glueing up columns in eight staves or pieces, the whole being glued together in the manner of Figure 4. We must here observe, that the workman must be careful to keep the joints out of the flutes, for being in the fillet, there will be more substance to prevent them from giving way. No. 1. is a section of the column at the top; and No. 2. a section at the bottom. After being supposed to be glued together, the octagons and mitres must be laid down correctly, in order to form the joints truly. Here are two bevels shewn, one for trying up the mitres, and the other for trying the work when put together.

Fig. 11. Shews the method of glueing up the base of a column, according to the following description. Let a course, consisting of pieces of equal lengths, be closely jointed together upon a plane surface or board, so as to be something more than the diameter of the most projecting moulding in the base, then glue the joints firmly together, and plane the upper surface smooth. Upon this course lay a second, with the same number of pieces as the first, closely jointed at the ends as before, and also to the upper surface of the lower course; glue down one of the pieces, so that the middle of its length may fall upon the joint of the two under pieces; then the others being glued on successively till the space is closed, a third may be repeated in the same manner. The horizontal joints of these courses must be so regulated, as to fall at the junction of two mouldings, forming a re-entering angle. When the glue is thoroughly hardened, the base may be sent to be turned. A base, glued up in this manner, will stand much better than one which has the fibres of the wood perpendicular. No. 1. is the plan of the base. The whole lines directed to the centre, shew the joints of the upper course; and the dotted lines tending to the same point, shew the joints of the course below.

Fig. 12. Shews the method of glueing up the modern Fig. 16. Ionic capital. No. 1. is the plan exhibiting the manner of placing the blocks. No. 2. is the elevation of the same. The plan is here inverted.

Fig. 13. Shews the manner of glueing up the Corinthian capital for curving of the leaves. No. 1. is the plan inverted. No. 2. the elevation. The abacus is glued up in the same manner as the Ionic capital, Fig. 12.

Fig. 14. Is the method of forming acylindrical surface, Fig. 14. without veneers, by equidistant parallel grooves, and by inserting slips of wood in the grooves. No. 1. exhibits the elevation, and No. 2. the plan.

Fig. 15. Shews the method of forming a conic body. The theory of this is no more than covering the frustum of a cone; the covering is formed by two concentric arcs, and terminated at the ends by the radii; the radius of the one arc is the whole slant side of the cone, that of the other is the slant side of the part cut off. Here the grooves are all directed to the centre, and filled in with slips of wood glued as before, the semicircle ABC below, is the plan; the arc HI must be equal to the semicircle ABC.

Fig. 16. Is the same for a smaller segment.

Fig. 17. Shews the method of glueing up a sphere or globe, by the same method. No. 1. the face of the piece; No. 2. the edge, shewing the depth of the grooves; No. 3. shews the mould for forming the pieces to the true curvature; No. 3. exhibits the faces of two pieces put together.

Circular headed sash frames in circular walls. The principle of a circular headed sash frame in a circular wall, depends upon the section of a cylinder, and the development of the surface as cut by another cylinder. In the formation of the radial bars, two of the sides are parallel planes, and the edges are portions of cylindrical surfaces, contained between the exterior and interior faces of the wall. To form the cylindrical surfaces of the concave and convex sides of the radial bars, it will be necessary to be informed, that the curves which direct the shape of the edges are portions of two different ellipses, formed by cutting two different cylindrical surfaces contained between the two sides of the cylindrical wall, and concentric therewith by two parallel planes, inclined at the same angle as the
plates of the bar, and having their distance from one another equal to the thickness of the said bar. And, consequently the ellipse, which directs the form of the concave edge of the bar, will have its lesser axis equal to the diameter of the interior cylindrical surface, and that which forms the convex edge equal to the diameter of the exterior cylindrical surface.

The circular bar, or, as it is improperly called, cod bar, depends on the development of the part of the cylindrical surface, formed by cutting a vertical cylinder by a number of horizontal concentric cylindrical surfaces, which gives the form of the veeeners, or thin slices of wood to be bent in thicknesses.

The head of the bar, when made by cutting a hollow cylinder, so that the side contained between the two cylindrical surfaces, that stand upon the exterior and interior sides of the plane of the sash, may be every where perpendicular to these surfaces, and to follow the true shape of the elevation of the window, and thus the angles will be easily moulded. But in order that there may be no variation of the mouldings in a circular sash frame, it is necessary that both the radial and circular bars, as well as the head, should be moulded upon the same principle as a hand rail, viz. by means of face and falling moulds; the face mould for the radial bars will be as before observed, and the falling mould will be a parallel slip of wood, straight in the edges, in breadth equal to the thickness of the bar. The falling moulds of the other parts must be made according to the development of the cylindric surfaces.

In Fig. 1, ABC, Plate CCCXXXVII, is the elevation of the head of the sash, and ABD the plan of the same. Bisect the arc ABC in B: draw BF perpendicular to AC, cutting the concave side of the plan at D: draw DG parallel to AC, and AG parallel to BF. Bisect the arc AB at 3, and draw 3 c parallel to BF, cutting GD at c, and the curve AD at c': draw the straight line A SK: draw AH making any angle with AK, and 3 I parallel to AH: make AH equal to AG, and 3 I equal to cc': draw the straight line HIK: join BK, and produce BK to L: draw AL perpendicular to BL, and join HL. Divide the arc AB into any number of equal parts as here, into 6: draw 1 a, 2 b, 3 c, &c. parallel to BF, cutting the inside of the head of the sash at a, b, c, &c. the inside of the plan at a, b, c, &c. and the straight line GD at a, b, c, &c. From the points a, b, c, &c. draw aa', bb', cc', &c. perpendicular to AL, cutting HL at a', b', c', &c. and AL at g, h, i, &c.: perpendicular to HL, draw a' a'', b' b'', c' c'', &c. Make a'' a', b'' b', c'' c', &c. respectively equal to ga, hb, ic, &c. and through the points a'', b'', c'', &c. draw the curve a'' b'' c'' d'' e'' f'': draw also the straight line p, q, r, parallel to AH, cutting AL at q, HL at r; draw rs perpendicular to HL; make rs equal to qr; draw LB perpendicular to HL, and make LB' equal to LB; join Hs, sa'' and B' f'', which will complete the concave edge of the face mould. In the same manner, by transferring the perpendiculars between AL, and the convex side AB respectively, to the perpendiculars upon HL, we shall have the points through which the concave edge of the face mould must pass, then tracing through the points so found, will complete the face mould R.

To draw the falling mould S, Fig. 2, for the convex side of the rail. Extend the arc AB, Fig. 1, with the divisions to the straight line AL, Fig. 2, and mark the extremities A, B, and the divisions 1, 2, 3, &c. Draw the lines AA', 1 a, 2 b, 3 c, &c. perpendicular to AB, from Fig. 1, transfer the distances GA, a a', b b', c c', &c. to Figure 2. upon AA', 1 a, 2 b, 3 c, &c. and draw the curve A a b c d e B will give one edge of the falling mould S; the lower edge will be found in the same manner.

To find the falling mould T, Fig. 3, for the concave side. From Fig. 1. extend p a, b b, c c, &c. to f, to Fig. 3. and place them upon PF, from P to a, b, c, &c. perpendicular to PF draw PL a, b m, c n, &c. From Fig. 1. transfer the perpendiculars q r, g a', h b', i c', &c. to Fig. 3. upon P L, a, b, c, &c. and draw the curve m n o p q r. From Fig. 2. transfer AN', 1 a', 2 b', 3 c', &c. to Fig. 3. upon a', b', c', &c. and draw the curve a'' b'' c'' d'' e' f' which gives the upper edge of the falling mould T. The under edge of T will be found in the same manner from the under edge of S. The upper line m n o p q r coincides with the top of the stuff, when the mould T is bent round, and the space between the curves a b c d e f which, and m n o p q r shows the waste of stuff at the acute angle of the piece.

Fig. 4. shows the application of the face mould R to Fig. 4.

The plank, the plane U shows the upper face of the plank; the plane V the edge; and the plane W the lower face of the plank; so that the two sides and the edge of the plank shews as if they were stretched out in one plane.

To apply the moulds, in order to square the stuff, that is, to make it stand over the plane, and opposite to its elevation, when set up in due position: Apply the mould first to the top of the plank at U, so that the chord line of the concave arc of the mould may coincide with AB, the edge of the plank, then draw the form of the mould upon the plane U; let g be one of the extremities of the chord; draw g h perpendicular to AB, cutting the aris line CD at h; make the angle C d equal to the angle LHA, Fig. 1, and the angle i h f in the plane W equal to L Y F, Fig. 1. make h f equal to i h, and draw f e parallel to CD. Then apply the mould to the plane W, so that the face may coincide therewith, and the chord with the line CD, and the point that was at g may now coincide with j; then draw the form of the mould upon the plane W;

To cut out the head in the same manner as directed for a hand rail.

The mould X, Fig. 1, is the mould for the radial bars, traced from the plane below; Fig. 5. shows the Fig. 5. method of applying it to the plane, which is exactly the same as if it were a hand rail.

Fig. 6. shows the method of tracing the veeeners of Figs. 6, 7, the cool or circular bar. Fig. 7. is the concave veeener. 8, 9.

Fig. 8. the convex veeener. Fig. 9. is the method of forming the edges of the veeeners, which are to be cut out to their thickness afterwards.

**Stairs.**

Stairs and hand-rails are most important branches in Stairs joinery; but before we enter upon their construction, it will be useful to point out some of the leading principles, without regarding the materials of which stairs are constructed.

The breadth of steps in general use is from 9 to 12 inches, or about 10 inches at the medium. In the best staircases, the breadth ought never to be less than 12 inches, nor more than 18. It is a general maxim, that a step of greater breadth requires less height than one of less breadth: thus a step of 12 inches in breadth will require a rise of 5½ inches; which may be taken as a standard by which to regulate those of other dimensions; so that multiplying 12 inches by 2½, we should
common practice would allow. The proportion of steps being thus regulated, the next consideration is the number requisite between two floors or stories: to ascertain this, we have only to suppose the breadth of the steps to be given, say 10 inches each, as depending on the space allowed for the staircase, and this, according to the rule laid down, will require a rise of 7 inches nearly. Suppose then the distance from floor to floor to be 13 feet 4 inches = 160 inches; then \( 45^\circ = 22\frac{1}{2} \) inches, which would be the number required. But as the steps must be equal in height, we should rather take twenty three rises, provided the staircase room would admit of it.

Stairs have several varieties of structure, which depend principally on the situation and destination of the building.

Dog legged stairs, are those that have no opening or well hole; the rail and balusters of both the progressive and returning flights fall in the same vertical planes.

Geometrical stairs, are those which have an opening down the middle, and of which every step derives its support from that immediately below, and from the wall of the staircase.

The steps of a stair consist of two parts, one being parallel, and the other perpendicular to the horizon. The part which is parallel is called the tread of the step, and the other part which is perpendicular, is called the riser.

The rough timber work which is used in the support of a stair, is called the carriage.

The string board, is a board fitted against the ends of the steps next to the well-hole, so as to make a complete finish; and the string which terminates the ends of the winders, is a veneer made in the form of a spiral back, with thick wood, so as to make it sufficiently strong.

The most certain method of carrying up a stair, whether of stone or wood, is to provide a rod of sufficient length to reach from one floor to the other, divided into as many equal parts as the risers are in number, and thereby to try every step as the work advances.

Hand Railing.

A hand rail is the upper part of the fence in a geometrical stair. In order that the hand may glide easily along the rail without straining the body, it is evident that the rail ought to follow the general line of the steps, and to be quite smooth and free from inequalities.

The principle of hand railing depends on the method of finding the section of a right cylinder, cyldroid, or prism, according to three given points in or out of the surface, that is, the section made by a plane through three given points in space.

The cylinder, cylindroid, or prism, is hollow, and equal in thickness to the breadth of the rail that is to the horizontal dimension of its section, and the ends or bases, the same as the plane or projection upon the floor.

The hand rail of a stair may always be formed of a portion of this cylinder, cyldroid, or prism, the base of which is the plane of the stair; for the hand rail itself must stand over the plane, it will therefore be contained between the vertical surface of the cylinder, cyldroid, or prism. And as the hand rail is got out in portions, so that each portion may stand over a quadrant of the circle, or ellipse, which forms the plane, we may also suppose such a portion contained between two parallel planes, so that the portion of the hand rail may be thus contained between the two cylindrical, or cylindroidic, surfaces, and the two parallel planes. The parts which are to be joined together to form the rail, are to be prepared in such a manner, that when set upon their place, all the sections which may be supposed to be made by a vertical plane passing through the axis of the cylinder, or cyldroidic, may be rectangles, and this is called the squaring of the rail; which is all that can be done by geometrical rules.

Now, as hand rails are not made of such portions of hollow cylinders or cyldroids, but of plank wood, we have only to consider how such portions may be formed from a plank sufficiently thick. As the faces of the plank are planes, we may suppose the rail contained between two parallel planes, that is, between the two faces of the plank. Then such figures are to be drawn on the sides of the plank, that, when the superficial parts are cut away, the surfaces that are formed between the opposite figures are portions of the external and internal cylindrical or cyldroidic surfaces. A mould made in the form of these figures, is called the face mould, which is only a section of the cylinder or cyldroid through three points in space.

The vertical, or cylindrical, or cyldroidic surfaces being formed, the upper and lower surfaces must next be formed. This is done, by bending another mould round one of the cylindrical or cyldroidic surfaces, generally made to the convex side, and drawing lines on the surface round the edges of this mould. Then the superficial wood is cut away from the top and bottom, so that if the piece were set in its place, and a straight edge applied upon the surfaces now formed, and directed to the axis of the well hole parallel to the horizon, it would coincide with the surface. The mould thus applied upon the convex side to form the top and bottom of the piece, is called the falling mould.

To find these moulds, the plan of the steps and rail must first be laid down; then the falling mould, which must be regulated by the heights of the steps; and lastly the face mould is ascertained by the falling mould, which furnishes the three heights alluded to.

Plate CCCXXXVIII. Fig. 1. is a dog-legged staircase. Plate No. 1. is the plan. No. 2. the elevation, shewing the cyldroidic rail strings under the steps, and the sling rod marked into equal divisions, for regulating the work in the process of putting it up. The dotted lines above the rail, drawn by the square, show how the centres of the arcs that form the ramp are found.

Fig. 2. Geometrical staircase with winders. No. 1. Fig. 2. is the plan. No. 2. the elevation and section. As the staircase is supposed to be cut through the middle, parallel to its length or longest dimension, it would be absurd to represent the whole elevation, as is frequently done; for this reason, only the farther half is represented, and the steps of the other half are shewn by dotted lines.

Fig. 3. Geometrical staircase without winders. No. 1. Fig. 9. is the plan. No. 2. the elevation. It is in such constructions as this and the last figure, where great nicety of workmanship, and skill in geometrical lines, are found necessary.

Fig. 4. A section of the rail and mitre cap for a Fig. 4. dog-legged staircase. The dotted lines are drawn from the section of the rail. No. 1. to the mitre. No. 2. in straight lines. From thence in the arcs of circles, to the straight line passing through the centre of the cap at right angles to the former straight lines, then perpendiculars are drawn, and made equal in length to the
perpendicu.lars. A curve being traced through the points, gives the form of the cap. The section, No. 1, is used in any kind of rail whatever.

Fig. 5. shows the section of a rail in a circular form. The sections of rails also form elliptic figures.

Fig. 6. is another form, called a toad's back rail, to be executed in the best houses. The top is generally cross banded, with coloured wood.

To draw the scroll for terminating the hand rail of a geometrical stair at the bottom. Let AB, Fig. 7, be the breadth given; draw AE perpendicular to AB; divide AB into eleven equal parts, and make AE equal to one of these parts. Join BE; bisect AB in C, and BE in P. Make CD equal to CE; draw DG perpendicular to AB; from F, with the radius FE or EB, describe arc cutting DG at G. Draw GH perpendicular to BE, cutting BE at O. Draw the diagonals DOK and IOL perpendicular to DOK. Draw IK parallel to BA: KL parallel to ID, and so on to meet the diagonals. From D as a centre, with the distance DB, describe the arc BG. From I as a centre, with the distance IG, describe the arc GE. From K as a centre, with the distance KE, describe the arc EH. From L as a centre, with the distance LH, describe the arc HP. Proceed in the same manner, and complete the remaining three quarters, which will complete the outside of the scroll. Make BR equal to the breadth of the rail, viz. about two inches and a quarter. Then, with the centre D, and distance DR, describe the arc RS. With the centre I, and the distance IS, describe the arc ST; and with the centre T, and distance KT, describe the arc TU, which will complete the scroll.

Fig. 8. Shows the construction of the curtail step, which is that under the scroll. a b c d represents the veneer which covers the riser; c f h is the nosing of the cover, or horizontal part of the step; i k l is the face of the string-board; and m n o the projection of the nosing.

Fig. 9. Shows the cover-board for the curtail step; a b c d and e f g h in dotted lines represent the plan of the scroll; o p q r s the nosing of the curtail step: t u v the nosings and the ends of the risers. The circle 1, 2, 3, 4, is described from the base of the scroll, and divided into equal parts, equal to the distances of the balusters from centre to centre; and lines are drawn to the centre of the scroll, in order to ascertain the middle of the balusters, by giving a regular gradation to the spaces. The whole of the spiral lines in this and in Fig. 9, are drawn from the same centres as the scroll.

Three heights from the base being given on the surface of a cylinder, or through three given points on its surface, to find a section of the cylinder, the heights of these points from the base being given.

Let A B C, Fig. 1, and 2. Plate CCCXXXIX, be the base of the cylinder, and A, B, C, the seats of the three points, of which the heights are a b c. Draw AD, BD, and CE perpendicular to the chord AC; make AD equal to a, BG equal to b, and CE equal to c. Produce CA and ED to meet each other in F. Draw BH parallel to CF, and GH parallel to EF; and join FH and produce it to i, if necessary. In CF take any point K, and draw KL perpendicular to CF, and KL perpendicular to EF, cutting EF at M. About K as a centre describe the arc MN, cutting CF at N, and draw NI. Join F, with the distance FI, describe an arc at L, and join FI. In the arc ABC take any number of points, from which draw lines parallel to FI, meeting the chord CF. From these points in the chord CF draw lines parallel to CE to meet EF. From these points draw lines parallel to FL, equal in length to the line parallel to FL; and through the extremities draw the curve EPD, which is the section of the cylinder required. The angle which the section now found makes with the plane ACED, is equal to the angle CNI.

Fig. 1. No. 1. is the plan of a part of a geometrical stair with winders and flys below and above, with the rail marked upon the plan. No. 2. is the falling mould, found in the following manner. ABC is the semi-circumference of ABC, No. 1. extended in a straight line; AD and CE are each in length equal to the breadth of one of the flyers extended in the same line; EF, perpendicular to ED, is the height of twelve steps, viz. to the heights of all the windows and two of the flyers. Draw AI perpendicular to AD; make AI and FG each equal to the height of a step. Draw GH perpendicular to FG, and make GH equal to the breadth of one of the flyers. Join FH, HI, and ID. Draw BK perpendicular to AC, cutting HI at L. Make LM at the discretion of the workman; through M draw OMP, meeting ID in P, and produce FH to O. Make P a, P b, O c, O d each equal to ID or HF. Divide a P into any number of equal parts, beginning at a, and P b into the same number of equal parts, beginning at P; and draw lines through the corresponding points of division, and they will form a parabolic curve. Divide c O and O d in the same manner, and form another parabolic curve; and thus the curves and the straight line a d will form the under edge of the falling mould. Make MN equal to the thickness of the falling mould, and through the point N draw the upper edge parallel to the lower edge, and thus complete the boundaries of the falling mould.

Make AV any distance, at the discretion of the workman, say 6 inches. Produce BM to K, cutting the upper edge of the falling mould at X. Bisect BV in Q. Draw QR and VW parallel to BX, cutting the upper edge of the falling mould at R and W.

Draw KTS parallel to EV. Make KT, TS, respectively equal to BQ, QV. Draw TU and SY parallel to KM, cutting the under edge of the falling mould at U and Y.

As one of the joints of the rail piece generally stands over the middle of the semicircular plan, and the other joint not over the place where the straight and circular parts meet, but three or four inches advanced into the straight part, in order to make a stronger joint, by using straight bolts or screws instead of circular ones; in laying down the plan of the rail for the face mould, we must first lay down the circular quarter, and then add the straight part, which is shown by AV in the construction of the falling mould. It is obvious that the falling mould depends in some measure on the fancy of the workman. The reason of raising it above the line 1, is, because if the rail were made the same height above the steps over the circular part of the plan as over the straight part, it would approach nearer to the nosings of the steps of the winders than to those of the flyers. It is evident that the ends of the steps might be so narrow in the circular part, as even to cause the rail to coincide with the nosings of the winders, while the under side of the rail would be two feet and upwards from the nosings, supposing the rail to be one height throughout, both in the straight and circular part; the height being supposed to be regulated from the top. The curves a b and c d are entirely at the fancy of the workman, some making them longer and some shorter.

In No. 3. the construction of the falling mould make No. 3.
Fig. 1.

No. 2.
a, b, c equal to the quadrant AB; No. 1. and draw a v a tangent to the arc a, b at a, and make a v equal to a v, No. 2. and the arc a, q equal to the straight line AQ. No. 2. Draw the radii o x and b, z, which will be a right-angle. Draw v, v parallel to o x. Make v, v equal to the breadth of the arch, as shewn by the plan, No. 1.; and draw the concave side of the plan v' a' q' b'. Then, having the seats of three points v, g, b', and the heights VW, QR and BX in No. 2. we may now proceed to find the face mould in the same manner as in finding the section of a cylinder, Fig. 1. and 2.; viz. draw the chord b', v', and draw v, v, and b', b, perpendicular to b, v. Make w, w, g, r, and b, x respectively equal to VW, QR, and BX, No. 2. Join x w and b, v, and produce them to meet each other in s, and join x s. Draw r i parallel to x s, and q i parallel to b, s. Join i, s, and produce b', v' and s, i to meet in f; and join x f; and proceed to complete the face mould, which is the section of a cylinder, in the same manner as in Fig. 1. and 2. as is plain by the small letters instead of the large ones.

Fig. 1.

No. 4. Shews the construction of the face mould for the upper part of the circle, which is the same as in No. 3. only the heights must be taken downwards, and from the lower side of the falling mould.

Fig. 1.

No. 5. Shews the application of the face mould to the plank, according to the following description. This diagram exhibits the two sides and the edge of the plank sketched in one plane, as shewn for the circular sash-frame in a circular wall. W is the plane of the top of the plank, X that of the edge, and Y the under face of the same. Previous to commencing the operation of cutting out the rail, the plank must be first bevelled on the edge. In this case, for the lower piece, it must be taken off the under edge, according to the angle b', v', n, No. 3.; that is, the two planes W and X must form an acute angle equal to the angle b', v', n. Place the face mould No. 3. upon the plane W, and make the chord line coincident with the edge AB, that is, the extremities of the concave edge to AB. Draw e d on the edge of the plank, making the angle B e d equal to the angle f x b', No. 3. Having drawn the lines on the top, round the face mould, apply the same point that was at c d on the other side, and bring the chord to coincide with the edge CD. Then the plane of the mould coinciding with the plane W of the plank... lines on the plank round the edges of the face mould as before. The lines being thus drawn, the superfluous parts that were on both sides of the mould are to be cut away, in such a manner as to form the surfaces of a cylinder on both sides. The falling mould constructed at No. 2. must be bent upon the convex side, and lines drawn upon that side round the edges of the falling mould. The superfluous wood must be cut off from the top of the piece, according to the upper line, by means of a square or right-angle; but, in squaring, the edge of the stock of the square must be always placed parallel to the axis of the cylinder. The other edge will be found by guaging the piece to its thickness on both sides, which is generally about two inches. 

JOINVILLE is a town of France, and principal place of a district in the department of the Upper Marne. The town is surrounded by the river Marne, and contains several good houses, and some streets that are tolerably wide. The church, which is an old building, is a mixture of Greek, Gothic, and Norman architecture. It has a handsome spire, all the ornaments of which, and even the pillars, are covered with slate. At the north end of the town, there is a neat bridge of three arches over the Marne, and there is a fine mall of trees near it, on the banks of the river. A canal passes through the town. The town contains 700 houses, and 3086 inhabitants.

IONA, Icolmkill, I-columb-kille, more correctly Y or I, is a celebrated island of the Hebrides, situated on the south-west side of the island of Mull, from which it is divided by a channel half a mile wide. By Bede, who is believed to have died in the year 762, it is named Hii, or Hiy, for the punctuation of vowels had not then been introduced; and in the annals of Ulster, which are of later date, it receives the designation of Isc and Aoi. However, in the records of Scotland down to the middle of the 16th century, in inscriptions contemporary with that period, still to be seen upon the island, and by the neighbouring inhabitants, it is simply called Y or I. This is said by etymologists to be the Irish for island; that I was aspirated by Bede to H'yi; and I-thon, also the Irish for the island of waves, being pronounced I-on, was by the monks readily latinized Hyona. Iona likewise appears on monumental inscriptions a little anterior to the Reformation; but that name is now entirely lost in the neighbourhood. By some of the ancient Irish and Danish writers, it is designed the Holy Island; and its modern appellation Icolmkill signifies the island of the cell of St. Columba, which does not seem to have been unknown to Bede. This island is two miles and a half in length, by little more than a mile in breadth, and contains a superficial area of about 1500 Scotch acres. The surface is unequal, rising into cumbines; and the most elevated part is about 400 feet above the level of the sea. A light sandy soil prevails. Upwards of 500 acres are in occasional cultivation, and afford abundant crops of barley and oats, besides which, the pasture of the island is celebrated all over the vicinity. Notwithstanding the lateness of sowing the grain, harvest is early in August. Adamnan relates, that barley sown in June, by command of Columba, ripened in the beginning of August, which, however, he ascribes to a miracle; and he alludes to the abundance of fruit. Great variety of beautiful and valuable minerals are found on Icolmkill, among which are a small vein of coal; and Mr. Raspe observed an efflorescence of copper. Fine white marble, semi-pellucid when reduced to thin plates, is received for windows; it cuts freely, receives a good polish, and, except for the loss of colour, which is converted to a yellowish cast, resists the action of time. There are extensive rocks of sienite on the south-west shore, which will afford blocks of any dimensions, of vivid colour, extremely hard, and susceptible of a high polish. Of this substance all the remnants of antiquity, of which she shall immediately treat, are constructed. Rocks of beautiful serpentine also stretch along the southern extremity, of considerable hardness, an agreeable green clouded with other colours, and suitable for slabs or sculptures. Its quality has been compared to that of the ancient serpentine, but although masses of large dimensions might be procured, it would not be without much labour, on account of the solidity of the rocks. In the Port-macr-aich, a creek where Columba landed, there are found nodules of a gneiss on the Marnic, called the Port-macr-aich stone, from the size of a pea to that of an apple. These are of a green colour, of a smooth soft appearance when polished, and are made into trinkets of various kinds. Many are worn by the Hebrideans as amulets, sometimes set in silver. They believe that a certain charm attends their presence, and they say that their colour
JONES, John Paul, Chevalier of the French order of Military Merit, and of the Russian order of St Anne, a distinguished officer in the navy of revolutionary America, and afterwards a rear-admiral in the service of Russia, was the son of Mr. John Paul, a respectable gardener. He was born at Arbignon, in the parish of Kirkbean, and stewardry of Kirkcudbright, in the month of July 1747, and received the rudiments of his education at the parochial school. The contingency of his residence to the shore of the Solway Firth, inspired him with an early predilection for a seafaring life; and while yet a mere child, he hoisted his flag on board his mimic ship, and issued audable mandates to his imaginary officers and crew, with all the consequence of a legitimate commander. Nor was he content with this. As his skill in manœuvring improved, he ventured to criticise the nautical knowledge of practical sailors; and in the eager and confident tone with which, from the eminence on which he took his station, he thundered forth his orders to the vessels which were entering the port at Carse-thorn, might be remarked the ardent and enterprising mind of one who felt that he was born to future command.

At the time of which we speak, the town of Dumfries carried on a very considerable trade in tobacco with America; and as the Nith was not navigable to foreign vessels, the cargoes were unshipped at Carse-thorn, near the mouth of that river. There, from his earliest years, Paul had opportunities of conversing with mariners from the discontented colonies; and it is probable that he thus first imbided that enthusiastic attachment to the United States, and those revolutionary principles, which exerted so decided an influence on his conduct when he grew up to maturity, and eventually led him to renounce his allegiance, and raise his hand against the country which gave him birth.

His partiality to a sailor's life was so determined, that his friends resolved to indulge it; and accordingly, at the age of 12, he was sent across the Firth to Whitehaven, where he was bound apprentice to Mr. Younger, a respectable merchant in the American trade. His first voyage was made on board the Friendship, Capt. Benson. His course was steered for the Bahamas, and before he had completed his 15th year, he had landed on the shore of that country which he was destined to adopt as his own. His home, while the ship was in port, was the house of an elder brother, who, having married a native of that country, had previously settled there. Here his early prepossessions in favour of America were confirmed, and from that period, as he afterwards expressed himself to Baron Van der Capellan, that became "the country of his fond election."

In the mean time, his intelligence and good conduct acquired him the esteem and confidence of his employer, who promised to give him a substantial proof of his favour, by promoting him to the command of a vessel; and he would have kept his word, had not the embarrassed state of his affairs deprived him of the power to do it.

Our adventurer, being at length freed from the trammels of apprenticeship, made several voyages to the coast of Africa; but he soon became disgusted with a traffic which had too long been the disgrace of civilized nations, and confined his services to the command of vessels engaged in a more reputable and legitimate commerce.

In the year 1773, he went to Virginia to arrange the affairs of his brother, who had died there without leav-
Jones, John Paul.

Jones, John Paul.

...to anchor in the Solway Firth, almost within sight of the trees which sheltered the house in which he first drew the breath of life. Early next morning, he rowed for the English coast, at the head of 31 volunteers, in two boats, with the intention of destroying the ship (about 200 sail) which lay in the harbour at Whitehaven. In this daring attempt he would probably have succeeded without difficulty, had not the strength of the opposing tide retarded his progress so much, that day began to dawn before he could gain the shore. He dispatched the smaller of the two boats to the north of the port to set fire to the vessels, whilst he led the remainder of the party in person to the more hazardous duty of securing the fort, which was situated on a hill to the south. It was a cold morning; and the sentinels, little aware that an enemy was so near, had retired into the guard-room for warmth, affording Jones an opportunity to take them by surprise, of which he did not fail to avail himself. Climbing over the shoulders of the tallest of his men, he crept silently through one of the embrasures, and was instantly followed by the rest. Their first care was to make fast the door of the guard-room, and their next to spike the cannon, 36 in number. Having effected this without bloodshed, they proceeded to join the detachment which had been sent to secure the vessel, and, finding that false alarm had deceived them from executing their orders, Jones instantly proceeded to set fire to the vessels within his reach. By this time, however, the inhabitants were roused, and the invaders were glad to retreat, leaving three ships in flames, of which one alone was destroyed.

Of all our hero's exploits, there is not one which reflects so much discredit on his name as that which we have just now mentioned; for, although it is lawful for a commissioned officer to annoy the enemy of his sovereign by all possible means, there is something extremely revolting in the idea of a man's deliberately stifling all his early associations, and availing himself of his familiar acquaintance with the place of his youthful enjoyments to effect its destruction.

On the same day with this adventure, another memorable occurrence took place, which contributed, for a time, to add greatly to the odium which the first had brought upon his character, but which, in the end, also served to prove that he was possessed of the most disinterested and heroic qualities. In cruising off the coast of Galloway, it occurred to him that, if he could get into his power a man of high rank and influence in the state, he should be able, by retaining him as a hostage, to ensure the American prisoners of war more lenient treatment than was threatened by the British government. Knowing that the Earl of Selkirk possessed a seat in St. Mary's Isle, a beautiful peninsula at the mouth of the Dee, and being well informed with regard to the political connections of that nobleman, he destined him for the subject of his experiment. With that view, he landed on the Isle, about noon, with two officers and a few men; but before they had proceeded far, he learnt that his lordship was from home, and that there were none but ladies at the house. Finding his object frustrated, he now wished to return; but his crew were not so easily satisfied. Their object was plunder; and, as they consisted of desperadoes in a very imperfect state of discipline, and with whom it would have been dangerous to contend, he allowed them to proceed. He exacted from them, however, a promise that they should be guilty of no violence; that the men should not enter the house, and that the officers, after having made their demand, should accept of what might be put into their hands without scrutiny. These conditions were punctually obeyed. The greater part of the Selkirk plate was carried off in triumph by the crew, and Paul Jones was, for a time, stigmatised as a disinterested man; but he nobly vindicated his character, by taking the earliest opportunity of purchasing the whole of it, out of his own private funds, and remitting it safe to its original owner without accepting the smallest remuneration. National prejudice has misrepresented this transaction; and in order to heighten the popular indignation against our hero, it has been common to state, that his attempt on the person, and as it was supposed, the property, of Lord Selkirk, was aggravated by ingratitude, his father having eaten of that nobleman's bread. Nothing can be more false. Neither Mr. Paul, nor any of his kindred, ever was in the Earl's employ, or had ever the most distant connection with his lordship or his family; and in a correspondence which took place between our hero and Lady Selkirk relative to the restitution of the plate, a most honourable testimony was gratefully paid by the latter to the Captain's character.

The day succeeding the two events, just mentioned, Paul Jones encountered the Drake, a king's ship of 20 guns, in Carrick Fergus bay. On finding that a very brave resistance, in the course of which the English captain and his first lieutenant were mortally wounded. With this and another large prize, Captain Jones returned to Brest, after an absence of 28 days of very active service, in which, besides taking and destroying many valuable vessels, he had thrown the coasts of Scotland and Ireland into consternation, occasioned the Irish volunteers to be embodied, and obliged the English government to expend considerable sums in fortifying the harbours.

A tear of hope and disappointments followed. The French ministry, to testify their good will to the United States, had promised to furnish Paul Jones with a ship, in which, however, he was to display the American flag; but, after various written memorials, no progress seemed to have been made towards the fulfilment of this engagement. At length he determined to apply in person, and having gone to Paris, he soon obtained the command of the Duce de Duras of 40 guns. The name, however, he changed to Le Bon homme Richard, in compliment to the wise saying of Poor Richard, "If you have your business done, come yourself; if not, send." In this vessel, badly manned, and not much better furnished, Paul Jones sailed as Commodore of a little squadron, consisting, besides his own ship, of the Alliance of 36 guns, the Pallas of 32, the Serf of 18, the Vengeance of 12, and two privateers, which requested leave to share the Commodore's fortunes. After taking several prizes, the Serf, the privateers, and at length the Alliance deserted the squadron. The Commodore's good fortune, however, did not desert him. On the 15th September, he was, with his own ship, the Pallas, the Vengeance, and several prizes, at the entrance into the Firth of Forth, where they made every necessary disposition to seize the guard ship, and two cutters, that rode at anchor in the roads, and to lay Leith, and perhaps Edinburgh, under contribution. The wind, which was fair, in the night, opposed them in the morning. However, on the 16th, the little squadron continued all day to work up the Firth. At this time, a member of the British Parliament observing them from the coast of Fife, and mistaking them for king's ships, sent off a
boat to inform the Commodore that he was greatly afraid of Paul Jones, and to beg some powder and shot.

Our hero, much amused with the message, sent him a barrel of gunpowder, with a civil answer to quiet his fears, and an apology for not including shot in the present. Next morning, at day-break, every thing was in perfect readiness to commence the engagement, and two tacks more would have brought the strangers alongside their enemies, when, at that critical moment, a sudden gale of wind swept down the Frith, raging with such violence, as completely to overpower them, to sink one of the prizes, and drive all the rest of the squadron fairly out to sea. By this failure, the captains of the Pallis and Vengeance were so much disheartened, that they could not be prevailed on to renew the attempt.

Continuing their cruise, after various adventures, the squadron suddenly discovered the homeward bound Baltic fleet, off Scarborough castle, escorted by H. M. S. the Serapis, and the Countess of Scarborough. After a long engagement, in which Paul Jones displayed the most astonishing skill, intrepidity, and presence of mind, the Countess of Scarborough struck to the Pallis, and the Serapis to the Bon-homme Richard, which latter ship was reduced to so shatter'd a state, that next morning, after all hands had left her, she went to the bottom. The Serapis was not in much better condition, the Commodore having, with his own hands, lashed the two ships together, to prevent the enemy from availing himself of his superiority in weight of metal. The Commodore now took the command of the Serapis, erected jury-masts, and with some difficulty conveyed his prizes to the Texel. Paul Jones, who never suffered the interests of his fellow-citizens to be lost sight of, exerted all his influence with the French court to have it arranged that his prisoners should be exchanged against American prisoners in England, and he completely succeeded. Dr. Franklin, the minister of the United States at Paris, soon cheered his heart, by writing to him, that "he had then completed the glorious work he had so nobly begun, by giving liberty to all the Americans who then languished for it in England." On this occasion, too, the King of France directed his ambassador at the Hague to communicate to Commodore Paul Jones the high personal esteem he bore for his character, especially for his disinterestedness and humanity.

The captain of the Alliance being ordered to Paris to answer for his insubordination, Jones took the command of that vessel; but he now found himself environed with dangers. The Dutch were summoned to deliver him up to the vengeance of the English government, as a pirate and a rebel; and they were most reluctantly constrained to order him out to sea, where an English squadron was watching to pounce upon him as their certain prey. The acceptance of a commission from the King of France would have saved him from this dilemma, and the ambassador from his most Christian majesty repeatedly urged him to adopt that alternative, but he thought his honour engaged to decline it. He would not, at whatever risk, abandon the flag of his beloved America. He, however, contrived to make his escape, passing the Straits of Dover, and the Isle of Wight, before the very beards of the English fleets.

Towards the end of 1780, our hero sailed for America, in the Ariel, with important dispatches, and having made his passage the Triumph, an English vessel of 20 guns, forced him to strike.

A little before this time, the King of France had testified his approbation of Paul Jones' services, by presenting him with a superb gold sword; and a letter from M. de Sartine now reached the President of the United States, requesting liberty "to decorate that brave officer with the cross of the order of military merit." The demand was laid before Congress, and a law having been passed on the 27th February, according to it, he was formally invested by the Chevalier de la Luzerne, at a public fête given to the members of that legislative body. In April following, on the report of a committee, Congress passed a vote of thanks to the Chevalier John Paul Jones "for the zeal, prudence, and intrepidity with which he had sustained the honour of the American flag; for his bold and successful enterprises to redeem from captivity those citizens of America who had fallen under the power of the enemy; and, in general, for the good conduct and eminent services by which he had added lustre to his character, and to the arms of America."

During the remainder of the war with England, he had no opportunity to signalise himself. After it was over, Congress, as an expression of gratitude, caused a gold medal to be struck, with appropriate legends and devices, to perpetuate the memory of his valour and services.

In 1787, the United States having charged the Chevalier with a mission to the court of Denmark, he set sail for that country in the month of November, and, passing through Paris in his way, was strongly solicited to assume the command of the Russian fleet in the Black Sea. Soon after his arrival at Copenhagen, a courier, sent express by the Empress Catharine, conveyed to him an urgent invitation to St. Petersburgh. Although he saw many reasons for declining to engage in the service of that Potentate, he was flattered by the offer, and felt himself bound at least to thank her Majesty in person. He therefore set out instantly for her court by the way of Sweden; but, at Greshelham, found the passage of the Gulf of Bothnia blocked up by ice. After several unsuccessful attempts to proceed to Finland by the islands, he conceived that it might be practicable to effect his object by doubling the ice to the southward. The enterprise was formidable and altogether new; but our hero was not easily daunted. Without making known his intentions to his companions, he set sail from Greshelham one morning very early, in an open boat about 30 feet long, followed by a little one to haul over the ice. Towards evening, having got nearly opposite to Stockholm, our adventurer, producing his pistols, ordered the astonished boatmen to pursue the route which he had secretly devised. Resistance was vain, and he was obeyed. All night the wind was favourable, and they hoped to reach the coast of Finland in the morning; but they found themselves opposed by an impenetrable barrier of ice. Neither was it possible, from the state of the weather, to return. The only resource was to make for the Gulf of Finland. When night came on, they steered by the aid of a pocket compass, lighted by the lamp of the Chevalier's carriage; and at the end of four days, after having lost the smaller of their two boats, they terminated a perilous and fatiguing voyage at Revel in Livonia.

The Chevalier was graciously received at the court of St. Petersburgh; and, no longer opposing the wishes of the Empress, attached himself to her service, under this single condition, "That he should never be condemned unheard."

He proceeded, without delay, with the rank of rear-
admiral, to take the command of the fleet stationed at the Liman, or mouth of the Dnieper, and oppose the Turkish fleet under the Capitan Pacha. On the 26th May 1788, he hoisted his flag on board the Wolodimer. His squadron was supported by a flotilla under the Prince of Nassau, and land forces under Prince Potemkin. Our limits forbid us to follow Admiral Jones through this campaign. It afforded him many opportunities of displaying his characteristic intrepidity and professional skill; but mean jealousy and malignant cabals deprived him of much well-earned glory. He was, however, invested with the order of St. Anne, as an acknowledgment of his fidelity; and, on his arrival at St. Petersburgh, he was told that he was destined for a more important service. Disgusted, however, by the intrigues of selfish men, he left Russia in August, 1789, and never returned.

The remainder of his days he spent partly in Holland, and partly in France. He collected a number of important documents relative to the public transactions in which he had been actively concerned; and, as if he had foreseen that he was not to be long-lived, he devoted much of his leisure to the arrangement of his affairs, and to the preparation of papers, which should exhibit his character and his services in their true light to his friends and to posterity. He died at Paris of a water in the chest, in July, 1792, having barely completed his forty-fifth year. His funeral was attended by a deputation of the National Assembly, and an oration was pronounced over his tomb by M. Marron.

Among the Admiral's papers were found Memoirs of his life, written with his own hand; a most interesting literary production, which it is in contemplation with his friends to present entire to the eyes of the public.

The above sketch has been drawn up from some of the documents above referred to. (O. T. Δ.)

IONIAN ISLANDS, is the name given to the islands in that part of the Mediterranean, between the coast of Greece and the island of Sicily. There are seven detached islands along the shore, which are ranked among the Ionian islands; namely, Corfu, Santa Maura, Ithaca, or Thiaiki, Cephalonia, Zante, and Cerigo, together with several islets, extending from about 30° to 40° N. Lat. and from 19° 30' to 23° 10' E. Long. But this, perhaps, may be more properly considered a political association than an arrangement to be recognised in geography, unless it were restricted to narrower limits, where the junta position of Santa Maura, Ithaca, Cephalonia, and Zante, would naturally admit of it. Corfu and Paxo are removed at a considerable distance north-west, and Cerigo more to the south-east, with few intermediate points of approximation. The number included under the general name of Ionian Islands has been different at different times; and there were formerly annexed to the jurisdiction under which they were placed five sea-port towns on the neighbouring continent,—Bucintro, Gomenitza, Parga, Presessa, and Vronita.

The climate of these islands is in general temperate; but, at certain seasons, the transitions from heat to cold are so sudden, that the inhabitants are compelled to use great precautions against their effects. Copious rains, attended by thunder, commence about the same period as winter in Britain; yet roses blow during the coldest weather. Hot and scorching winds sometimes destroy the vegetation; violent squalls are continually felt in the channels separating their respective shores; and the hurricanes on the west and north-west

of Paxo have rooted up the olives, and obliged the islanders to substitute vines. All the islands are subject to earthquakes, which have repeatedly overthrown cities, and buried their inhabitants in ruins. Scarcely a month passes without shocks being experienced in Santa Maura. Zante was almost totally destroyed by one in 1790, and in the summer of 1811, several shocks daily were common. The sphere of their operation is not extensive, seldom affecting any but the isles in the vicinity, or the neighbouring continent; and sometimes it is confined to a single island exclusively. They are also described to be undulations, rather than vibrations or concussions. Water is scarce throughout the islands. There is no large stream, or river discharged into the sea; and the inhabitants are supplied from wells, or, in many parts, with cisterns excavated from the rocks to retain the residue of the rains. Corfu, which extends about 35 miles in length, and is esteemed the chief of the Ionian islands, contains a population of 60,000 souls. Paxo, distant 8 miles south of its extreme point, is 18 or 20 miles in circumference, and has about 4000 inhabitants. Santa Maura, lying considerably to the south-east, is about 50 miles in circuit, and contains about 20,000 inhabitants. Ithaca is interposed between it and Cephalonia, extending 18 miles in length, and having a population of 8000 souls. Cephalonia exceeds all the others in size; it is 100 miles in circuit, or, following the curvature of the coast, about 150, and its population is equal to that of Corfu. Zante lies 6 miles to the south of Cephalonia, and is about 12 miles in length, and 30 in circumference, but more populous in proportion than the others, as its inhabitants amount to 40,000. Cerigo lies at the distance of about 150 miles from Zante, in a straight line S. S. E., but farther by navigation. It is about 17 miles long, 10 broad, 45 in circuit, and its population amounts to about 10,000 persons. Antipaxo lies south-east of Paxo, the Strophades between Zante and Cerigo, and Cerigotto to the east of the latter. Almost all the Ionian islands are of irregular figure, presenting coasts which are rugged and of difficult access, with several harbours for the most part insecure. Towards the north of Corfu there is a deep bay, with a narrow entrance, called Port Guvime, at the bottom of a great road, which, in the year 1799, contained the Russian and Turkish squadrons. Here it has been proposed to establish a naval yard, from the facility with which materials could be brought to it at small expense; and it is well defended by military posts and batteries. A spacious bay nearly separates Ithaca into two parts. Cephalonia has several ports formed beside its long peninsula, but some of them are choking up by earth washing down from the hills, together with the sand of the sea. Cerigo is begirt by rocks and shoals, which are sometimes fatal to mariners, and the navigation of the channels separating the islands from each other, or dividing them from the continent, appears difficult and hazardous.

Some of the islands in the Mediterranean are of volcanic origin; but this is not said to have been the case with those now under consideration. A large portion of them consists of lime-stone. There is a quarry of grey marble in Corfu, and a vein of coal has also been found there. Petrifications seem numerous, and the islands are penetrated by spacious caverns, where the abundance and diversity of stalactites exhibit most fantastical forms, resembling the works of art.
There are petroleum wells in Zante, near the shore, about 10 miles from the city, which produces yearly 50 or 100 barrels of 150 pounds each. The largest is about 50 feet in circuit, but only a few feet in depth; and there are others at a short distance, wherein the petroleum is continually accumulating. Sulphureous exhalations, and the frequent earthquakes, denote uninterrupted subterraneous fires.

The Ionian islands are in general hilly and unequal. The highest ground of Cephalonia rises 3000 feet above the level of the sea. Much of the surface is rocky, some parts stony, and there are fertile grounds interspersed.

The extensive plain of Zante, in particular, resembles one continued vineyard, with patches in tillage or pasture, and is the source of great wealth to the inhabitants. The principal productions of the Ionian islands are grain, fruit, cotton, honey, wax, oil, hareskins, and lambskins; but, of the first, the quantity is not nearly adequate to the consumption of the inhabitants, who draw their supplies from the neighbouring continent, as the inequality of the surface affords little scope for the improvements of agriculture. Nevertheless, every advantage is taken of the smallest portions of soil. Terraces are formed on the declivities, their culture is carefully attended to, and rich harvests are obtained. Vines and olives grow universally in great luxuriance, and are the chief objects of notice; the first on account of their fruit for home consumption and export, the second for the oil afforded by them. The grapes are of a diminutive kind, known in Britain, when dried, by the name of currants, of which the average crop is about seven million of pounds in Zante alone. In some years it is nine or ten, and has even amounted to twelve million. They are gathered somewhat earlier than other grapes, and spread out for eight or ten days previous to being packed; but there are instances of the harvest being totally ruined by rains. Cephalonia produces five or six million pounds of the same fruit; Ithaca only 5,000 or 6,000; Cephalonia likewise yields 80,000 or 90,000 pounds of honey yearly; and, in the island of C time, it was computed there were 1,480 bee hives in the year 1811. About 100,000 pounds of cotton of very fine quality are produced in Cephalonia, 3,000 hare skins, and 5,000 lamb skins.

The fish on the coasts of Corfu, Paxo, Santa Maura, and some of the other islands, and large eels caught in the inland pools afford a plentiful subsistence to the inhabitants. Seals retreat to the caverns of Zante, where they are hunted for the sake of their skins. This island seems to be more infested with noxious animals than the rest. A small kind of musquito, whose bite is extremely painful, appears in myriads; a species of centipede, described as an inch or an inch and a half in length, is said to inflict a mortal wound. A singular spider is also much dreaded here, though probably with little reason, which, like some others of the genus, constructs a door with a hinge, and lies in wait behind it, for the prey. Its poison is reputed very active, and the only cure is the excision of the wounded part. Scorpions, lizards, and small snakes, are not uncommon. Birds of prey, and poultry in general, are scarce, nor are there many of other species, except birds of passage, and water fowl among the marshes. Mules are employed in agricultural operations, and horses and cattle are brought from the continent. Goats and sheep are numerous in Cerigo; and the wild animals of the islands are foxes, hares, and rabbits.

In regard to the products of human industry. Salt works are carried on to a great extent in Corfu at three different places, Potamos, Kasstrados, and Lefkiko, or Dragotino, producing what is both of coarse and fine quality. The Venetians had 800 pans at Lefkiko, from which fine salt was obtained; and it has been suggested lately, that very great profits may be derived from its fabrication. Five or six thousand tons of the same commodity are made in Santa Maura. Oil of olives is expressed in large quantities in Corfu, Cephalonia, and a small portion in almost all the rest of the islands. It is observed that the quality of the oil depends greatly on the nature of the soil, and the mode of manufacture. Thus, from the greater care of the inhabitants, that of Paxo is esteemed the best. The oil of Corfu is divided into four classes; first, eatable oil, which is selected from the second, the ordinary oil of commerce; thirdly, kernel oil, produced by passing kernels a third time through the press, which is, in general, of a chestnut-brown colour, and in a congealed state. It is of inferior quality, and serves for little else than the manufacture of soap. The fourth kind is black and thick, which is not put into casks until it has been mixed with a third of kernel oil. Abundant harvests produce towards a million of jars, or 250,000 casks annually in Corfu. About 25,000 or 30,000 casks of oil are made in Cephalonia, commonly green and thick, and not affording above 3,000 or 4,000 from that quantity of good eatable oil. Paxo produces only wine and oil; Santa Maura wine, oil, and salt. From 30,000 to 35,000 casks of wine, both white and red, are made in Cephalonia yearly. The red, consisting of 15,000 casks, is dry and spirited. Of the remaining 20,000, there are 12,000 of agreeable taste, and 8,000 muscadel, one-third of which is of inferior quality. In the same island, 3,000 or 4,000 casks of brandy are made annually; there are two establishments for the preparation of liqueurs from aromatic herbs and flowers. Two kinds of liqueurs are likewise made in Cerigo. As the cotton of Cephalonia is very fine, muslins equal to those of India may be manufactured of it. Coarse cotton cloths are likewise manufactured here, and in the neighbouring islands, among which is nankeen, used by the Venetians for clothing their troops. Silk stuffs, and carpets of goats' hair for the Venetian gondoliers, are made in Zante.

The trade of the Ionian isles is either reciprocal among Commercials, themselves, or foreign, with the Morea and Albania, or with Venice and Trieste, and other ports of Europe. Exports. They export their own produce and manufactures, such as great quantities of currants, to England, the trade in which has increased much of late years, including also the produce of part of the neighbouring continent: Salt from Corfu and Santa Maura, chiefly to the Port of Guro at the mouth of the Po. Traffic in oil has been more flourishing since the year 1804, and most part of it is exported to Venice, whence it is distributed to various quarters of the continent. Brandy is sent from Cephalonia to Trieste, and to Venice, Leghorn, England, and Russia. Cotton is carried from the same islands to Zante, where it is manufactured into goods suitable for turbans, and thence exported to Constantinople. The honey is principally consumed at Venice, hare skins are sent to Corfu, and lamb skins to Trieste and Senigaglia.

The imports of the Ionian islands consist of cattle and grain from the Morea, in proportion to the necessities of the population. Pasturage is scanty in the greater number of the islands. Paxo does not produce grain adequate to one month's consumption, and it remained a long time uninhabited, owing perhaps to its natural sterility. Between 4000 and 5000 peasants an-
now established, and men of considerable information dwell in Corfu, Ithaca, and Zante. The islanders in general are fond of shows and exhibitions; they even had an Italian opera, which maintained its place notwithstanding the war. But there is a great intermixture of eastern manners to be seen; and amidst the restrictions of sociality, the women are so strictly watched in some of the islands, as scarcely to be accessible by their nearest relatives.

The population of the Ionian islands is dispersed in several cities, villages, and hamlets. The former sometimes have the name of their respective islands, as Corfu, a very strong place, containing about 15,000 inhabitants; Zante, which in every thing resembles an Italian city, containing 16,000 or 18,000; Santa Maura, containing 6000; and Paxo, containing 4000. The principal town of Cephalonia, Argostoli, has a population of 5000; Vathi in Ithaca, of 2000; and Kapsali in Cerigo, of 4000 souls. Strophades contains only a monastery, which is a tower 90 feet square and 60 high, defended by a battery of four small cannon; and behind the gate, which consists exclusively of plates of iron, is a draw-bridge with a guard-house. This monastery is inhabited by about 40 monks, the sole population of the island. Parties of pleasure resort thither from Zante; but no women are allowed to land, nor are any female animals permitted to be brought on shore. The dwellings of the inhabitants of the Ionian islands are, for the most part, very much dispersed, and few are collected together into villages. Churches, chapels, and priests, are extremely numerous. Though we suspect the truth may be exaggerated, Cerigo is said to have 260 of the former, and 165 of the latter.

The Ionian islands are all celebrated in the writings of the ancients, under the names of Coreyra, Paxus, Leucadia, Ithaca, Cephalonia, Zacynthus, and Cythera. Some of them were independent states, and some subordinate to other governments. In the fictions of the poets also, they are stated to have supplied their respective quotes for the siege of Troy. After experiencing various reverses of fortune, under the authority of the Greeks and Romans, these islands were subdued by the Venetians, who had for a long time the pre-eminence of maritime power in the Mediterranean.

Desirous of keeping them in a state of absolute dependence, a provost or proconsul was sent from Venice, who frequently paid more attention to his own profit than the advantage of the people; dissensions were rather fomented than quelled; and civil wars at last resulted from the imprudence of the governors. The fall of the Venetian republic subjected the Ionian islands to the French, and notwithstanding the substitution of their democratic principles, attended by unfavourable impressions, for a despotic aristocracy, they were relieved from an oppressive yoke, and by the aid of a strict police harmony was restored. By the war between France and Turkey, the French were expelled in 1798, and the islands taken under the mutual protection of Russia and the Ottoman Porte in 1800, under the name of the Ionian Republic of the Seven Islands. But the contending interests of these two empires opposed the permanence of this arrangement: a rivalry for pre-eminence arose among the islands, anarchy was making rapid advances, and the public safety endangered, when the aid of the Emperor Napoleon was solicited by the inhabitants. On the arrival of his troops, the protection of the republic was transferred to Russia exclusively; a constitution was framed, and an executive government appointed.
Meantime a new candidate for the sovereignty appeared in Ali, the Turkish Pasha of Joanna, who had long cast a wishful eye on the Ionian islands. He had gradually rendered himself master of an extensive territory surrounding his capital; he had expelled the Venetians from four of their continental stations, and nothing was now more essential to his security and aggrandisement than the completion of this favourite object. He besieged Santa Maura, and took an active part against the Russians, whose unfortunate war with France enabled the latter to resume the protection of the Ionian republic in 1807. The maritime superiority of Britain, however, was speedily interposed to intercept supplies and reinforcements: Santa Maura, besides, was regularly invested in 1810, and a French garrison captured, though with some loss to the assailants. The reduction of all the islands successively followed, until nothing remained of the whole republic except Corfu alone.

On the restoration of general peace in Europe in the year 1814, provision was made for new arrangements: and by a treaty between Russia and Austria, Erussia and Britain, signed at Paris in 1815, it was agreed that the Ionian Islands should be recognized as an independent state, and put under the protection of Great Britain; that the custody of the fortresses, and the command of the army, should be committed to his British majesty; and that a code of civil and political institutions, such as were supposed most beneficial to the interests of the islanders, should be framed. These terms have been fulfilled; and very recently a deposition from the islanders has arrived in this country, in order to attain the final adjustment of all that remained to be carried into execution under the treaty. (c)

IONIC ORDER. See CIVIL ARCHITECTURE, Vol. VI, p. 603, and Plate CLIN.

JONSON, BENJAMIN, (or as his name is commonly abbreviated, Ben) the dramatic poet, was born in the early part of the year 1573. His grandfather was a man of some family and fortune, originally settled at Annandale in Scotland, from which place he removed to Carlisle, and was subsequently taken into the service of Henry VIII. His father, who is believed to have been about the court, suffered a long imprisonment under Queen Mary, probably for religion, and was deprived of his estate; but became afterwards (as Wood informs us) "a grave minister of the gospel." Our poet was a posthumous child, and came into the world about a month after his father's death.

His mother, in somewhat less than two years after the death of her first husband, married a master bricklayer of the name of Fowler. From this step-father, it could hardly be expected that our poet should have received a liberal education; but there was happily a generous friend, (whose name, however, is not recorded,) who sent him at his own expense to Westminster School. At that seminary, Jonson's youthful genius was submitted to the guidance of the illustrious Camden; and we find him in more than one part of his writings alluding with reverence and affection to the guardian of his favourite studies.

Mr. Gifford, in his memoirs of this poet, supposes that he left Westminster about the age of sixteen, and that he went from thence at once to the university. The person who had hitherto befriended him, procured for him, as Aubrey informs us, an admittance at Cambridge; but whatever might be its value, it was found inadequate to his support, and he was obliged too soon to quit the university, from the imability of his parents to assist him. How long he continued at College cannot be known. Fuller says a few weeks; but Mr. Gifford reasonably infers, from the expressions of obligation which he uses to the members of the university, that his connection with them must have extended to a much longer period. It seems undeniable, however, that poverty cut short the term of his education, and that he returned from college to follow the vocation of his father-in-law,—that of a bricklayer. Several stories that have been told by his biographers about the manner of his leaving this occupation, turn out, when examined, to be perfectly groundless. There is no truth in Fuller's account, of his being found by some gentlemen with the trowel in one hand and Horace in the other, and of his 'being manaced by their bounty,' to follow his ingenious inclination. Equally absurd is the story of his being tutor to the son of Sir Walter Raleigh, and of his being sent home in a basket whilst asleep with intoxication, by the witty contrivance of young Raleigh,—an anecdote which Mr. Malone himself has been weak enough to repeat. Jonson's own account of his early life is, that he could not endure the occupation of a bricklayer; and having enlisted as a volunteer in the army, went over to Flanders.

His stay in the Low Countries did not extend much beyond one campaign; he had however an opportunity of signaling his courage, having (as he told Drummond) encountered and killed an enemy, whose spoils he carried off in the sight of both armies. From the Low Countries, he returned with the reputation of a brave man, a smattering of Dutch, and an empty purse. He was now about nineteen, and betook himself to the stage for support, at first as an actor, but undoubtedly at no great distance of time as a writer. In the meantime, however, he was involved in a second affair of the sword, which was likely to have terminated more fatally than the first. Having had a dispute with some person, probably a brother player, he was challenged by his antagonist to the field. Jonson killed his opponent in a duel; but he himself severely wounded, and thrown into prison for murder. During his confinement, he was beset by the artifices of a Papish priest, who persuaded him to embrace the Catholic faith, and it was not till twelve years afterwards, that he was again brought back to the mother church. He was annoyed also, during his imprisonment, by the visits of spies, who must have been employed about him, in consequence of his connection with the Romish priest; as in those days the idea of Popery carried that of conspiracy along with it to the minds of all sound and zealous Protestants. He does not appear, however, to have remained long in prison. The prosecution for murder was probably dropped.

On his release, he thought proper to marry. He was now only in his 20th year, and his means of support cannot be supposed to have been affluent. It is not indeed perfectly clear, whether he was at this period merely an actor, or whether he wrote for the stage, in conjunction with other dramatic poets, who had been longer in the employment of the managers. The latter supposition seems to be very probable. It was at that time the custom for theatrical managers to have writers in regular and permanent hire, who frequently united their talents in the fabrication of the same piece, and to whom money was advanced upon the credit of the work as it was shewn or reported. It has been found impossible to ascertain the names of the dramas, in which Jonson exerted his earliest efforts for the stage, either singly or in partnership. The first piece that can be appropri-
told in the list of his plays, is the comedy of Every Man
in his Humour. This play had been popular, and had
been acted eleven times by Henslowe's company of
players, between the 25th of Nov. 1596, and the 10th
of May in the succeeding year. Before this period,
however, he must have written for the stage, both alone
and with others. The comedy of his youth was success-
ful in its first production. The lofty tone of defiance to
criticism which the author assumes in the prologue, and
his subsequent alterations and high improvements of the
piece, are eminently characteristic of Jonson. The
prologue breathes all his personal pride, and discloses
the energetic ideas of poetry which he early entertain-
ed. His changes of the piece announce the still ripen-
ing progress of his taste and his patience, to elaborate
and finish even what had satisfied the public judgment,
though not his own. The scene of Every Man in his
Humour, had at first been laid in the neighbourhood of
Florence, and the characters were Italian. Jonson, in
altering the piece, made the scene and characters Eng-
lish, and rendered the whole effect more congruous
and native. The play, thus re-modelled, was acted in
1598 at the Black Friars, and Shakespeare's name stands
at the head of the principal performers in it. This pe-
riod, the year 1598, is that which the commentators
of Shakespeare have fixed upon as the era of Jonson's ac-
quaintance with Shakespeare, an acquaintance which,
according to their account, commenced with an act of
kindness on the part of Shakespeare, which was re-
turned with ingratitude by Jonson. Mr. Gilchrist and
Mr. Gifford have on this subject answered all the chal-
ges of ingratitude brought against the memory of Jon-
son, with a shew of facts which appears to us to be de-
cisive. Ben Jonson was not altogether unknown to the
world in 1598, as Mr. Malone has asserted; he was,
on the contrary, very well known, and ranked among
the most eminent dramatic geniuses of the time.
As such a pre-eminent genius, he is expressly
mentioned by Meares at this very period. He had not
indeed, as his censurers tell us, (at the very time when
they describe him as a person altogether unknown,) he
had not killed Marlowe the poet in a duel, and he had
not been young Raleigh's tutor; but he was well-
known already as an able writer for the drama; and
there is not a shadow of proof that he was indebted to
Shakespeare, either for his introduction to the players,
or for the extension of his popularity. To anticipate
something in our account of this eminent man, we con-
ceive the readers of Mr. Gilchrist's and Mr. Gif-
ford's respective vindications of him will be left with-
out a doubt upon their minds, that the proofs of ma-
lice towards Shakespeare, which Jonson's writings are
supposed to contain, have been as falsely and gratuit-
uously assumed as those of Shakespeare's ideal services
to Jonson.

His next piece was entitled, Every Man out of his
Humour, which was exceedingly well received. Three
distinct notices of Jonson appear in Henslowe, the the-
atrical manager's memorandum book for the year 1599,
which are nearly contemporary with the appearance of
this comedy. The sum of 40 shillings was advanced
to him and Decker for a play, which they were writing
in conjunction; a like sum for another, in which Chet-
tle was joined with them; and a third sum for a tra-
gedy, which he was probably writing alone. None of
these are now extant. His "Comical Satire (as he en-
titles it) of Cynthia's Revels," was acted in 1600. Its
chief objects of ridicule seem to have been the ceremo-
nious fopperies of courtiers; and the offence which it
excited, we should have expected to have been in that
quarter; but the real enemies which it raised up to
Jonson, were his fellow-labourers for the theatre, Mar-
ston and Decker, who conceived that the principal per-
sonages in the pieces were designed to ridicule them-
selves. His angry rivals were concerting a plan of
revenge for this injury, how far it was real or imagi-
nary we have now no means of ascertaining, when Jon-
son anticipated their attack, by bringing out his "Poet-
aster."

This attack upon Decker and Marston was favour-
ably received; and its only disagreeable consequence
to the author, was the accidental offence which it gave
to some of the military and legal profession, who chose
to consider their callings as satirized by the poet. It
appears, that from the persecutions of the latter he had
some difficulty in getting free. The Satironomastick,
in which Decker replied to the Poetaster, was rather an
angry than an amusing attack, and though its bitter-
ness excited a temporary interest, it cannot be con-
considered as having formed any reverse in the tide of Jon-
son's popularity.

About this time, says his biographer already quoted,
Jonson began to acquire that turn for conviviality, for
which he was afterwards noted. Sir Walter Raleigh
had instituted a meeting of "choice spirits" at the Mer-
maid, a celebrated tavern in Friday-street. Of this
club, which combined more talent than perhaps ever
met together before or since, Jonson was a member,
and here for many years he repaired with Shakespeare,
Beaumont, Fletcher, Selden, Cotton, Carew, Martin,
Donne, and many others, whose names even at this
distant period call up a mingled feeling of reverence and
respect. Here were Jonson's wit combats with Shake-
peare's; and in allusion to those joyous scenes of con-
versation, Beaumont breaks out in raptures in his letter
to Jonson:

What things have we seen
Done at the Mermaid—hence the jest that have been
So nimble and so full of subdue flame,
As if that every one from whom they came
Had meant to put his whole wit in a jest.

Upon the accession of James, he was one of the ear-
liest poets who were employed to grace the public fes-
tivities that were exhibited in honour of the new sove-
ign, with appropriate compositions. In those times,
the visit of the sovereign to any public corporate body,
or to any of his gentry or nobility, was generally re-
ceived with an entertainment, in which the pageantry
was emblematic, and often accompanied with poetry.

Even when the sovereign was not present, there was
a poetical play of imagination in public festivities,
which is altogether unknown to the colder manners of
later times. Jonson's reputation stood so high, that
few public solemnities were thought perfect without
his assistance. For this assistance, it is well known
that our poet received periodical sums, not only from
public bodies, but from several of the nobility and gen-
try. A year seldom passed without some royal pro-
gress, and corporate bodies were frequently encouraged
to feast their sovereign. As these visits were irregu-
lar, and without much previous notice, it became an
object of no small importance to have a person always
at command, on whose abilities they could rely for an
entertainment that should neither disgrace themselves
nor their guests. Hence sprung the several pensions
which were regularly paid to Jonson, and which may
be considered in the light of retaining fees. His pen-
sion from the city alone amounted to an hundred no-
bles a year. King James seems to have looked
with no ordinary degree of favour on the learning and inge-
nuity of Jonson; but, at an early period of the reign, our
poet was accidentally involved in a disagreeable af-
fair, which did not seem to augur that he should ever
be the favourite poet of the court. He had taken some
slight share, along with Marston and Chapman, in the
comedy of *Eastward Hoe,* a play in which some satiri-
cal expressions about the Scotch gave so much offence,
that Chapman and Marston were committed to prison
as its authors. Jonson, though he had no share in the
offensive passage, thought himself bound in honour to
share the fate of his associates, and voluntarily accom-
panied them to prison. They were all speedily liber-
ted, but not before a report had gone abroad, that it
was intended to punish them by blighting their ears and
noses. Had this barbarous sentence been passed, the
mother of our poet intended to have given him a po-
ison, and to have drank it along with him. From such
a parent, it has been justly observed, that he must have
derived no small share of that personal resolution which
so strongly marked his character.

His *Sejanus* (for we need not stop to notice the dates
of his masques and entertainments) was first acted in
1603, and unfavourably received. In its first state, the
author himself informs us that another hand had a
good share in it; but when recast, with alterations en-
tirely his own, it was again brought on the stage, and
experienced a much better reception. It was not pub-
lished till 1605. It is remarkable, that it is not divided
into scenes in any of the editions; it has neither exits
nor entrances, and is, upon the whole, the most invol-
volved and puzzling drama, in its internal arrangements,
that was ever produced. *Sejanus* has all the learning
of Jonson, and it also displays the peculiar force and
loftiness of mind that belonged to him. It has pas-
sages of great eloquence, and a masculine tone of mo-
rituality; but its merit is more historical and oratorical
than, strictly speaking, dramatic. We come, how-
ever, (anno 1605) to the very brightest period of his
dramatic career, when, in the course of a few years,
successively came out, his *Volpone,* or *Fox,* his *Epi-
cene,* or *Silent Woman,* and his *Alchemist.* The Fox
was first acted at the Globe theatre in 1605. It kept
the stage till the dispersion of the players by the Pu-
ritans: Was revived at the Restoration, and made its
last appearance in the life-time of the elder Colman,
but unfortunately at a period when the dramatic taste
of the age was giving way, not to the hatred of the Pu-
ritans, but to the growing affection of the public for
the exhibition of quadrupeds on the stage. The *Epi-
cene,* or *Silent Woman,* also continued a popular fa-
ourite in the best times of the stage. Garrick attempt-
et to retrieve it also from the neglect which it began
to experience in the latter part of the last century, but
is said to have been unsuccessful. From what is re-
corded of his power of acting in Abel Druger, it must
be supposed that he succeeded better with the Alch-
mist. Indeed, we cannot willingly believe public taste
to be at any period so degraded as to make the *Alch-
mist* unwelcome. The *Alchemist* has, indeed, been
well pronounced in the words of Tate, *to be astonish-
ing. It has a full popular breadth of humour—a vast
strength and well adjusted complexity of characters—
and a rich minuteness of information respecting the
profound mummeries of alchemy, that leave the mind
as much amused with the learning, as exhilarated by
the wit and humour of the poet. He speaks like an
initiated mystic in alchemy, whilst he makes us laugh
at its exposed imposture; and he exhibits so much
knowledge of the pretended secrets of the science, that
we feel as if he had taken to pieces in our presence
some curious automaton, which had deceived the eyes
of the ignorant with an imitation of life.

*Catiline,* which followed the *Alchemist,* was brought
out in 1611. It was not, as Mr. Malone asserts, deserv-
edly damned; it met, indeed, with opposition, but
continued on the stage until the civil wars. Whatever
may be the faults of *Catiline* as a tragedy, it has pages
of Roman eloquence, which neither deserves to be
damned nor forgotten. We allude particularly to the
speeches of Petreius, which are not, as has been rashly
asserted, mere translations from the classics. That one
which begins with the following lines is wholly origi-
nal:

The strains and needs of Catiline being such
As he must fight with one of the two armies
That then had near inclosed him; it plea'd fate
To make us the object of his desperate choice,
Wherein the danger almost pos'd the honour.
And as he rog'd the day grew black with him,
And Fate descended nearer to the earth.
As if she meant to hide the name of things
Under her wings, and make the world her quarry.
At this we rouse'd, lest one small minute's stay
Had left it to be inquire what Rome was,
And, as we sought, arm'd in the confidence
Of our great cause, in form of battle stood;
Whilst Catiline came on, not with the face
Of any man, but of a public ruin.
His comitance was a civil war itself,
And all his host had standing in their looks
The paleness of the death that was to come;
Yet cried they out like vultures, and urg'd on,
As if they would precipitate our fates.

In the same year King James settled upon Jonson a
pension for life, of a hundred marks per annum. This
has been in courtesy termed his appointment to be lau-
reate, and perhaps it was so. Hitherto, any one who
chose to write verses for the court, called himself, and
was often called by others, the laureate; but the title
has since been confined to those who receive a pen-
sion.

In the summer of 1618, our poet made a journey to
Scotland; and in the April of the following year, after
having resided for several months on visits to different
noblemen and gentlemen who showed him hospitality,
reserved his last visit for his poetical acquaintance Wil-
liam Drummond of Hawthorne. From the record
of his conversations with Drummond, no pains have
been spared to draw matter of detraction upon his char-
acter. It has certainly been Jonson's fate to be calum-
niated. His memory has absolutely been loaded with
persecutions sufficient to shake the confidence of a
mind conscious of its own virtue in that justice which,
it is common to say, that posterity exerts towards the
virtuous. At the late vindications of Jonson's memory,
who would not rejoice? It is from no wish to cavil at
those vindications, that we beg leave to differ in some
points from the sentiments which Jonson's latest editor
and biographer has expressed respecting Drummond.
Jonson came to the house of Drummond, who took
notes of his conversation, and threw them into his re-

*Tate's Preface to *Duke and no Duke.*
peradled to his indulgence. During the life of James we never hear of Jonson’s poverty; but, by the death of that monarch in 1625, he lost a most-indulgent and liberal patron. He was attacked, towards the end of the same year, by the palsy, and his decaying constitution also betrayed a tendency to dropsy. While this decay was coming on, he wrote his play The Staple of News. Though the language of this comedy is forcible, and the satire well directed, its plot labours under the same difficulties and defects as that of the plots of Aristophanes, which the poet had in view, namely a confusion of real and allegorical characters. The gossiping credulity of the age is, however, admirably held up to ridicule. While his wants and infirmities were increasing, he applied once more to the theatre, and produced his comedy of the New Inn in 1629-30. The fate of this drama was, to be driven by his enemies from the stage. An allusion to the king and queen, which was made in the epilogue of this play, awoke the slumbering kindness of Charles, and he instantly sent him a present of £100. The monarch also liberally accorded to our poet’s petition, that he would be pleased to make the 100 marks of his father £100; and he added, unsolicited, to the grant, a tierce of Canary wine.

Notwithstanding this accession to his income, his circumstances continued to decline together with his health. It is acknowledged, that he was utterly devoid of worldly prudence; what was liberally given him was lavishly spent. A dispute, in which he was involved with the architect Inigo Jones, contributed to embitter his last days, in which it appears that Jones was at least as vindictive as the offended poet. Under these melancholy circumstances he was employed in writing his Magnetic Lady, which appeared in 1632. It was indifferently received. There is, indeed, too much reason for acknowledging the remark of Dryden, that Jones’s last plays were his dotages.”

The Tale of a Tub was his last comedy that was submitted to the public (in 1633). It was not liked by the court, before which it was represented. The mantle of his comic inspiration was now worn thinness. Still, with his faint and faltering tongue, he continued to pay his annual duty to his royal master, and to compose occasional interludes. One of these, the light and sunny ray, which is his biographer, yet broke through the clouds which hung over his closing hours. In this he produced the Sad Shepherd, a pastoral drama of exquisite beauty; the better half of which, however, was unfortunately lost in the confusion that followed his death. This was apparently the close of his labours. Among his papers were found the plot and opening of a domestic tragedy, on the story of Mortimer, Earl of March, together with the Discoveries and Grammar of the English Language. His death took place on the 6th of August 1637, and he was buried on the 9th, in Westminster Abbey, in the north aisle, in the path of square stone opposite to the scutcheon of Robertus de Rios. His friends designed to raise a noble monument to his memory by subscription, and, till this was ready, nothing more was required than to cover his ashes decently with the common pavement stone which had been removed. While this was doing, Aubrey tells us, Sir John Young, of Great Melton, in Oxfordshire, whom he familiarly calls Jack Young, chanced to pass through the abbey, and not enduring that the remains of so great a man should lie without a memorial, gave one of the workmen eighteen pence to cut the words, “O rare Ben Jonson.” The subscription was successful, but the troubles of the civil war prevented the execution of the monument, and the
money was returned to the subscribers. Jonson in his
person was large and corpulent. He had, Aubrey says,
been fair and smooth faced, but a scurbinous humour
seems to have fallen at an early period into his face, and
to have seared it in a very perceptible degree. Randolph
the poet, and others of his admirers, traced a
resemblance in him to the head of Menander, as ex-
hibited on ancient medals.
Jonson, whatever his last biographer may say of the
candour and amiability of his dispositions, was cer-
tainly not endowed with the meekness and modesty
which are sometimes known to accompany transcen-
dent talents, and which disarm the envy that naturally
follows the possessor of great genius. Un fortunately as
he sometimes was, in being embroiled with his contem-
poraries, he seems, however, upon the whole, to have
been more fully and fairly appreciated in his lifetime
than he has generally been in the course of two suc-
ceeding centuries. He was deeply learned, and he was
laborious in the execution of his art. An invidious
conclusion has been too often drawn, that because
he was learned, he was pedantic; and because
he wrote upon fixed principles, he must necessarily
be for ever stiff and artificial. But the scholarship
which he brought to our drama was in many respects
subservient to the purest objects of excellence. He
brought the truth and simplicity of the ancient stage
upon our own, at a time when our dramatic poets had
nothing but extravagance and absurdity in the scenes
and incidents of their pieces, which they generally
drew from some novel or romance. His vein of hu-
mour was powerful and original; his sense of moral
truth, keen and sagacious. The latter quality of his
mind often preceded as the more dignified over his
humour; and he would often sacrifice ludicrous effect in
his pieces to give them the stern and severe graces of
propriety. He was happy in discriminating character
by its slightest shades of difference, as well as in pic-
turing it forth in bold, broad, and prominent forms.
His plots have a masterly conformation, and their com-
plex parts are adjusted with the firmest unity of de-
sign. His style on the stage is manly, though it is al-
most only in his shorter lyrical effusions that we find
him graceful and beautiful. It must, however, be
deleted from his merits, that his severity of manner
too often leads to harshness; that instead of interesting
pawans, he sometimes treats us to abstract displays of
humours in human character, which are neither amus-
ing nor edifying in their exposure; and that he
labours too minutely upon his important characters.
His lyrical poetry forms, perhaps, the most delightful part
of his poetical character. In songs and masques, and
interludes, his fancy has a wildness and swiftness that
we should not expect from the severity of his dra-
matic taste. It cannot be said, indeed, that he is al-
most free from metaphysical conceit, but his language
is weighty with thought, and polished with elegance.
Upon the whole, his merits, after every fair deduction,
leave him in possession of a high niche in our litera-
ture, and entitle him to be ranked (next to Shake-
spell) as the most important benefactor of our early
drama. (*)
IOORIA, is a seaport town in Guzerat, situated on
the Gulf of Cutch. A very brisk trade is carried on
between this town and Mandavse, as well as other
places on the Gulf of Cutch, and occasionally with
Bombay. The exports are principally cotton, ghee,
ol, and hides, to the southern ports; and coarse Dun-
garee cloth for Persia and Arabia. Its imports are

sices of all kinds, powder, lead, and cocoa nuts. The
vessels of Ioria carry from 50 to 60 caddies. The
larger vessels are unloaded at a place about three
miles from the town, and the goods brought to within one
mile of the fort by means of lighters. The value of the port
is about 30,000 rupees per annum. Ioria is subject to
the Rajah of Amran; and a treaty was entered into be-
tween this place and the British government in 1808.
See Hamilton's Gazetteer.

JOPPA. See JAFFA.

JORDAENS, Jacob, a celebrated Dutch painter of
historical and allegorical subjects, and bacchanalians,
was born at Antwerp in the year 1594: Nothing re-
markable concerning his parentage has been preserv-
ed; but at an early age he became a pupil of Adam
Van Oort, a native of the same city, who died in 1641.
Van Oort was a man of irritable temper, and coarse and
forbidding manners, whereby he not only lost the re-
gard of his pupils, among whom was the famous Ru-
bens, but forfeited the esteem of his friends. Jordaens,
however, from his own mild and pacific disposition,
could accommodate himself to the caprice of his master,
to which also an attachment to his daughter is suppos-
ted to have contributed. He married her soon after,
and henceforward began to apply with all possible assi-
Auality to his profession. Sandarart, indeed, in his Aca-
Aemia Nobilissimae Artis Pictoriae, seems to infer, that
it was perhaps to that sedulous attention which always
distinguished him, that he obtained so much of Van
Oort's favour.

Jordaens speedily employed his pencil on subjects
both sacred and profane, as well as those of his own
composition. Among the earliest specimens of his art,
was a painting of the Satyr from Aesop's Fables, who,
having entered a peasant's cottage, retreated in disgust
on seeing him blow hot and cold with the same breath.
and this work gained such celebrity, that it was engra-
ved by Luca Vastermann. Next he painted Christ
on the Mount of Olives, betrayed by Judas, and bound by
the Jews, while Peter with his sword struck off the
ear of Malchus, the high priest's servant: a night scene,
admirably executed. A parallel now began to be drawn
between Jordaens and Rubens; and the most skilful,
who were inclined to bestow the palm of invention on
the latter, ascribed the stricter representation of truth,
and more forcible expression, to the former. Perhaps
Jordaens had not equal opportunities of studying the
most celebrated works; for although he always enter-
tained a strong desire to visit Rome, the circumstances
attending on his marriage prevented him.

Rubens was accustomed to employ many other art-
ists in assisting him to complete his works, as they
gained access to him, for the purpose of receiving in-
struction. Jordaens appears to have been of this num-
ber. It is said, that Rubens occupied him for a consid-
terable time in painting designs for tapestries in dis-
temper after his own sketches; and Sandarart affirms,
that he was engaged by the King of Spain to execute
some tapestries for the royal palace at Madrid, a work
which he finished with wonderful elegance; but that
by addicting himself to this style, he weakened his
own knowledge of the principles of colouring, and
enfeebled the tints whereby he so accurately repre-
sented nature. Rubens being then the most flourishing
painter of the age, is accused of entertaining great
jealousy of his talents, and of having taken that me-
thod to depreciate them; but independent of this, be-
ing inconsistent with the general character of that emi-
inent artist, the works of Jordaens, executed at an ad-
Jordaens, a celebrated painter of the Flemish school, was born in 1593 and died in 1678. His works are among the most valuable in the history of art, and his influence on the development of the Dutch school of painting was considerable.

Jordaens worked with so much ease and expedition, that all Belgium began to be full of his paintings. He completed a fine representation of Pan and Syrinx, who was metamorphosed into a reed, within six days, though the figures were as large as life. A painting of Satyrs carrying cornucopia of fruit and grain, apparently of the same description, is equally celebrated for its harmonious proportions and colouring. He executed paintings for a banqueting-house for the King of Sweden; and another work for his native city, wherein a vast framework of mankind and animals was introduced. Jordaens was much employed in painting altar-pieces, many of which are yet preserved throughout the Netherlands.

This painter during his whole life was in constant occupation; but it is owing to the remarkable expedition with which he produced them, that the public are in possession of so many of his works. He is said never to have left his native city; and he died there in the year 1678, aged 84.

Jordaens was of a cheerful temper, and of a disposition particularly friendly and affable, and he enjoyed much gratification in the society of his friends. His industry enabled him to accumulate considerable wealth. He ranked high in his professional art; and he is thought to have carried the precepts of Rubens farther than any of his other pupils, Vandyke excepted. His compositions are full of taste and effect; his style brilliant and harmonious; and his designs are peculiarly characterized by truth and accuracy. He was most skilful in giving relief and rotundity to his figures; and from the nature of their execution, he is supposed to have studied the objects in candle light, or bright sunshine. For a free and spirited touch, no painter is accounted his superior. Yet Jordaens had conspicuous faults. His design, though distinguished by accuracy, is deficient in taste. He is charged with grossness of subject and form, and with images of low and common life. Jordaens, however, must be considered a great painter; for his beauties in every piece predominate over his imperfections.

JORDAN, a celebrated river of Asia in Palestine, which has been venerated from the most remote ages by Jews, Christians, and Mahometans. No river in the whole universe perhaps has attracted so much notice, the Ganges excepted; yet both its source and its expanse have proved the most embarrassing problems to modern geographers. Even the ancients themselves seem to have laboured under considerable difficulties regarding them. This is the largest river in Palestine. Its name, according to Beland, ought to be read Jor- den in Scripture; it is called Zarde by the Jews; and Schereia by the Arabs. St. Jerom affirms, and many others have followed him, that it rises from two sources, a mile asunder, the one called Jor, the other Dan, and that the name Jordan is compounded from them after the formation of the river by their union. Some authors interpret Jordan the river of judgment.

There is a mountainous and nearly uncultivated district called Hasbea, at the foot of Mount Hermon, or Jebel Sheik, among the mountains of Antilithus, containing a town of the same name, situated on a steep declivity. Not far distant are various streams, to which the source of the river is indefinitely ascribed. But that which seems to be so with greatest certainty is the river Hasbena, about half a league west of the town of Hasbea; for Europeans reject the opinion of the inhabitants of the country, that it is the stream Tellkady. Hasbea is situated five leagues south of Rascheia, and apparently at no great distance from Panias, or Baniass; but the geography of this part of Syria and Palestine is so obscure, that we are unable to point out the exact position of these places by positions well determined. The ancients believed, that the ample source of the river of Baniass, which springs in the vicinity of a remarkable rock, was that of the Jordan. According to others, however, the river rose from the small lake Phiala, now called Birkel-el Ram, two leagues east of the town; and Josephus relates, that Philip the Tetrarch threw a straw into it, which was absorbed, and discharged at what may be supposed the source of the river of Baniass. All these facts illustrate the difficulty of ascertaining the truth. Near Baniass, it is evident that several small streams contribute their waters to form the Jordan, which about three leagues below the town expands into a small marshy lake, which is enlarged or diminished by the melting of the snows in the mountains, or the evaporation occasioned by the heat of summer. This lake is the Samachonis of the ancients, and the waters of Merom of Scripture, and the Bahr el Houly of the moderns. Its circuit when full does not exceed 7 or 8 miles, and at times it is almost dried up. The river, now considerably enlarged, issues from it with a turbid stream, which is soon purified, by passing over a rocky bed, wherein its mud is deposited. About a mile from the lake, it is crossed by an ancient structure called Jacob’s Bridge, consisting of three arches, built of basalt, in a good preservation, which is said to derive its name from Jacob having returned by it from Padan Aram. This bridge is the mutual boundary of the Turkish Pachalies of Damascus and Acre; and at each end is a fortress, occupied by the troops of the respective pachae; but both were dilapidated by the French troops when they invaded Syria. Here the river is 6s feet wide, its current rapid and boisterous; but a modern traveller says, he found its breadth 35 paces in January. Indeed, in considering the dimensions ascribed to this river, too little attention is paid to the measures of different nations, as well as the season of observation; for there is sufficient reason to conclude, that it receives large ascensions from the melting of the snows. Here the banks of the river are finely wooded by trees, chiefly of the species Platanea; and the country becomes wild, mountainous, and entirely basaltic. Thirteen miles lower, the river passes through the beautiful lake Tiberias, or the Sea of Galilee, 18 miles in length, and issues from its southern extremity in a stream 40 paces wide. It now enters a fine plain called Al-Gaur, or El Gor by the Arabs, and soon after receives a considerable river, the Scheriat Manatra, formerly called Hieramack, or Janak, from the east, some leagues below the lake. The Scheriat Manatra is crossed by a bridge of five arches, which indicates that it is of considerable size; and at the west side there is a very spacious fortress, with a small garrison. Apparently the principal ascensions to the Jordan are henceforward from the east; but few of them are distinctly ascertained. Some considerable streams flow from the west. Below the Scheriat Manatra there is the Wady Mesh, which is discharged into it opposite Beisan, or Scythopolis, from the east; and still lower the Serka, which is the Jabok of the Jewish historians, and the boundary of the country of the Amorites. Between the confines of Syria and Arabia, the extensive valley,
bounded on each side by lofty chains of mountains, contains in its centre the Jordan, now pursuing a lagoon course through the space of 75 miles, from the lake Tiberias to the Dead Sea, into which it rolls the volume of its waters. The total course is about 125 or 130 miles. But the intermediate country in the latter part of it is so little known as that approximating its source; and no modern traveller, except Hasaelquist, seems to have beheld the efflux of the river, whose observations are restricted to its having there thrown out a quantity of willow. Probably he traversed the plain of Jericho to the Dead Sea, extending about three leagues in length, as he says that it is in general barren and level, with some small rising grounds interspersed; that the soil consists of greyish sandy clay, so loose that the horses sunk up to the knees in it; and that the whole surface of the earth was covered with salt, the same as in Egypt. All computations of the size of the Jordan, are taken from its appearance at the distance of several miles from the mouth. It there appears dull and turbid, flowing at the rate of about two miles an hour. So many discrepancies prevailed among the accounts of travellers regarding its breadth, that the only mode of reconciling them, is to suppose that it does not continue uniform for any considerable space, that their observations were made at different seasons, and have been given in the measures of different nations. According to Thomson it is 75 feet; Chateaubriand calls it 50 paces; but Shaw, who probably has been more minute, remarks, that excepting the Nile, it was by far the largest river he had seen in the Levant or Barbary; however he did not estimate it at above 80 yards wide, and three deep close to the brink; therefore combining the rate of its course with its size, he calculated that it would discharge six millions and ninety tons of water daily into the Dead Sea.

The natural history of the Jordan is not well explained, and there are few geological illustrations of the country which it traverses. Limestone, basaltic, different salts, and asphaltum, seem to be the more remarkable substances. The banks in some places are woody, and abounding in reeds, from which the Arabs obtain materials for the shafts of their lances and arrows; and the Turks employ the more slender kinds for writing. Wild beasts and game are exceedingly plentiful around Banias, and the huntsmen set fire to the reeds on the confines of the lake Samachonitis, to dislodge the wild beasts from among them. Lions, tigers, and bears, descend from the neighbouring mountains, to which must be added many other ferocious animals of prey. Chateaubriand found the waters of the Jordan bitterish; but though he drank a great quantity, he suffered no injury. They hold in solution the same ingredients as the Dead Sea, but in very small portions; nor is this surprising, considering that there are salt streams in the neighbourhood. It is related in Scripture, that a bitter stream, which ran through the plain of Jericho, was converted by the prophet Elisha to a limpid brook to fertilize the fields. Notwithstanding the mineral impregnations of the Jordan, it contains plenty of fish, which are sometimes carried down to the Dead Sea, where they perish. It is generally understood that the waters of this sea are alike pernicious to animal and vegetable life. Trollo affirms that he has collected the dead fishes as they were thrown on the banks; but Chateaubriand, having encamped on its banks, heard a noise towards midnight, which his companions from Bethlehem assured him "proceeded from legions of little fishes leaping towards the shore."

It is said that the peculiar quality of the Dead Sea is derived from a great mountain towards the southwest extremity, composed of numerous strata of salt, and that from a high rock, probably not distant from the mountain, an island of considerable extent may be discovered.

But whatever be the physical nature of the waters of the Jordan, the credulous have conferred on them the property of washing away sin. Originally this river only served for the necessities of the human race, and as a boundary to the restless tribes of the Jews; but it was viewed with peculiar veneration by succeeding generations. While the Christians had possession of Palestine, during the Crusades, its waters were carefully transported to Europe for the purpose of baptizing the families of Potentates. The Jordan is yet a place of great resort to those troglodytes who continue to visit the Holy Land, and they endeavour to bathe in the very spot where our Saviour was baptized by John. The pilgrims desire total immersion; but the female part of them only strip to their under garments, and let the water flow on their heads. The Greeks bathe at a place three or four miles distant from the other Christians, on account of a dispute concerning the precise site of the sanctified spot. It appears that, independent of other times, an annual excursion for bathing takes place on Easter Monday, when all the pilgrims, men, women, and children, leave Jerusalem in a great caravan, with the governor of that city at their head. The road leads past several places mentioned in Scripture; among which is the city of Jericho, now an incon siderable village. About half a mile from the river there is a ruinous convent, dedicated to St. John, up to which, according to tradition, it formerly flowed; but modern observers consider the fact improbable, from the height and steepness of its present banks. The pilgrims descend to a place still lower, yet their immersion is not accomplished without danger; and there are instances of many, who had entered the river inconveniently, being carried away and drowned. A tax is imposed upon each on the way to the river, and something is also exacted by the governors on their return. In the year 1807, fifteen hundred pilgrims visited Jerusalem; and bathing in the Jordan is always one of the principal objects of pilgrimage to the Holy Land. See Mariti, Viaggi, tom. iii. Shaw's Travels, p. 374. Pococke's Description of the East, vol. ii. p. 72. Thomson's Travels. Hasselquist's Travels. Volney Voyages, tom. ii. p. 279. Chateaubriand, Voyages, tom. i. La Roque, Voyage en Syrie. (c)

JOSEPHUS, the Jewish historian, was born in the first year of the reign of Caligula, A. D. 37, and was descended from one of the noblest families in Judæa. His father Mathias was sprung from one of the principal branches of the race of the priests, and his mother from the royal blood of the Asmonæans or Maccabees, who had held, for a considerable time, the supreme authority among the Jews. He speaks rather boastingly of his early proficiency in learning; and professes to have been able, at the age of fourteen years, to confer with the principal men of Jerusalem on the more intricate points of the law. At the age of sixteen, he united himself with a celebrated Essene philosopher, sharing, for the space of three years, in all the austerities of his sect; but, at the end of that period, he returned to Jerusalem, and attached himself to the sect of the Pharisees. In the 26th year of his age he made a voyage to Rome, in order to employ his influence in behalf
IPSCHWICH, formerly GIPESWICH, is a burgh town of England, and principal town of the county of Suffolk. It is situated on the side of a hill, on the northern bank of the river Orwell, and is about one mile long, and 3-ths of a mile broad, forming a portion of a circle round the bend of the river. The town is ancient, but well built; and the principal streets are clean, and well paved and lighted. Some of the houses are adorned, both externally and internally, with carved and stuccoed devices. The principal public buildings and establishments are the town-hall, the shire-hall, a new county jail, a palace belonging to the bishop of Norwich, an hospital, a market place, a custom-house, and a good library. The town-hall, which was formerly the parish church of St. Mildred's, is a very ancient building; and adjoining to it is a spacious council-chamber, with kitchens, &c. underneath. The walls, and the brick gate-way, are all that remain of Wolsey college, the site of which formerly comprised about six acres of ground. The market-place, which is large and commodious, was finished in 1814 from the designs of Mr. Brown. It consists of a series of buildings, on pillars, arranged round two quadrangular courts, and cost about £10,000.

The county gaol is an admirable building. Its boundary wall, which encloses ½ acres of ground, is 20 feet high. The prison consists of four wings, having spacious courts, about 75 by 45 feet, and three smaller ones, about 44 feet square. These different courts are seen from the keeper's house in the centre of the prison, from which there is an avenue 98 feet long to the turnkey's lodge, upon the top of which the executions take place. The house of correction has an airy situation near the burgh gaol, and has a boundary wall 17 feet high, and three court yards, each 50 feet by 30. Besides these public buildings, there is the town and borough gaol in Matthew Street, chapels for the Unitarians and Anabaptists, an assembly-room in Tavern Street, a custom-house on the quay, which borders the Orwell, and a handsome stone bridge, connecting the town with Stoke Hamlet.

Besides three charity schools, Ipswich has a school on Lancaster's plan, which was opened on the 8th July 1811 with 200 boys.

There are at present twelve parish churches in Ipswich, viz. St. Clement, St. Helen, St. Lawrence, St. Margaret, St. Mary at Elms, St. Mary at Kay, St. Mary at Stoke, St. Mary at Tower, St. Matthew, St. Nicholas, St. Peter, and St. Stephen. The monastic establishments were once numerous, but nothing more than their names have been preserved.

About a mile from the town is a good race course, which was sold in 1811 to several private individuals; and extensive barracks, capable of accommodating 10,000 or 12,000 men, have lately been erected for infantry and cavalry.

Extensive manufactories of broad-cloth and sail-cloth, were formerly carried on in this town, but they have long since declined; and malting, and spinning for the merchants of Norwich, are the only ones which are carried on. The chief trade of the town, which is still considerable, consists in malting and corn, and has the accommodation of a port and a quay; great quantities of wheat and other grain are annually shipped for the London market; a considerable timber trade was carried on for the use of the royal dock-yards, particularly Chatham; ship-building still flourishes, from building yards being attached to the port; the Greenland fishery is prosecuted with success; and though the coal
Ipswich.

The trade has decreased, yet more then 20,000 chaldrons of coal are annually imported into the town.

The river Orwell has the advantage of a tide, in general from 10 to 12 feet, and though it was formerly much neglected, yet it has been rendered capable of bringing vessels of large burden within a very short distance of Ipswich.

The civil government of the town consists of two bailiffs, a recorder, 12 justices, including the two bailiffs, a town clerk, the two chamberlains, two coroners, and 24 common councillors. It sends two members to parliament, and the right of election is vested in between 600 and 700 persons. Ipswich possesses many rights and privileges peculiar to itself, and an admiralty jurisdiction extending beyond Harwich on the Essex coast, and on both sides of the Suffolk coast.

Ipswich has five annual fairs, on May 4th and 18th, July 25th, August 22d, and September 25th.

Cardinal Wolsey was a native of this town. The population in 1811 amounted to 2,221 houses, and 13,459 inhabitants. See Oldfield's History of the Boroughs; The Suffolk Traveller; Tanner's Notitia Monastic; and the Beauties of England and Wales, vol. xiv. p. 230. IRAC. See Persia.

IRELAND.

History.

The materials for the history of Ireland, prior to the invasion of that country by the English, in the reign of Henry II. are so ill authenticated, so scanty and unconnected, and, in the very few instances where they are not so, they are so barren of interest and importance, that we cannot deem ourselves justified in dwelling upon them at any length. Nevertheless it would be improper to pass them over entirely; we shall therefore notice them cursorily, so far as they seem to us supported by direct evidence, or great probability, and as they are interesting and important from their connection with the more luminous portions of Irish history.

That the Celts either passed of their own accord, or were driven by the Goths, into Ireland, there is no reason to doubt; but it is not clear at what period this event happened, nor which of the two branches of the Celts colonized this island. It is also probable, that after the Goths of England had driven the Celts into Ireland, some tribes or families of the former passed over also; at least the traditions of the Irish—the names they give to some of their ancient inhabitants and invaders, and the names of many of the tribes, who, according to Ptolemy, possessed Ireland in his time, evidently point to a Gothic population. The first authentic glimpse we possess of Irish history, is drawn from Tacitus; according to him, an Irish prince, who had been obliged to leave his native country in consequence of a unsuccessful domestic war, endeavoured to persuade Agricola to invade Ireland, assuring him that a single legion of Roman soldiers could accomplish the subjugation of that country, or, more probably, of that part of it from which he came. The account of Orosius, that, in the fifth century, a number of Scythians, who had been driven out of the north of Spain by the Emperor Constantine, landed in Ireland, and there met with a people of the same origin and language with themselves, the Scyths or Scots, does not appear to rest on very good foundation, though there is undoubted evidence that Ireland, at least from the 4th century down to the 10th, was known under the appellation of Scotia, and its inhabitants under the appellation of Scota.

The period and the circumstances of the first introduction of Christianity into Ireland, notwithstanding the numerous, particular, and confident traditions of the Irish respecting St. Patrick, are not well authenticated. It has been supposed, from some passages in St. Jerome, that it was introduced in the 4th century; but if this was the case, its progress must have been very slow, and its hold on the minds of the inhabitants very feeble; for, in the 6th century, there appear to have been scarcely any vestiges of it. Soon after this period, however, Christianity made rapid progress, and manifested its influence by effects much more decidedly advantageous to the interests of religion and learning than any which it produced in the other Christian countries of Europe. The number of learned and holy men that sprung up in Ireland, and of monasteries and academies that were founded in it, during the fifth and two following centuries, was so great, and so many were the missionaries who proceeded from it to propagate the Christian religion, that it was dignified with the title of Inulae Sanctorum, or the island of Saints. Attracted by its justly acquired character, and by the tranquillity and prosperity with which Ireland was favoured, amidst the barbarism and warfare of the rest of Europe, men distinguished for their piety and learning took refuge here. According to Bede, in the year A.D. 646, and A.D. 616, there were many of the Anglo-Saxons, both nobles and of the middle classes, left their own country, and took up their abode in Ireland, either to indulge their taste for reading, or to lead a life of stricter religious observance; all of these the Scots received and treated in the most hospitable manner, lending them books, and affording them gratuitous instruction and sustenance.

What effect the labours of these pious and learned men produced on the character of the great mass of the people, we are not informed; but it is probable that the political state of the country would most thoroughly counteract their most zealous and judicious efforts to enlighten and civilize the inhabitants, (if they were made,) and would keep them down, at least to the level of that intellectual and moral state, in which the great mass of all the nations of Europe at that period existed.

Respecting the political state of Ireland at this time, our information, where it is accurate, is general; for at this time we must carefully separate the fullness and minuteness of the romantic history of this country, from the brief and naked circumstances of its authentic history. That it was divided among several independent chieftains, or princes, there can be no doubt; but the number of these is uncertain, and probably varied at different times. Whenever any of these princes gained a great accession to his territories, he assumed to himself the title of King of Ireland, but the title never was supported by the power, and generally continued for a very short time. There were several subordinate lords under each of the chief princes; in the principality of Munster alone there were eighteen; under these again there were other chieftains. But the power of the superior lord over his feudatories was very precarious,
In the year 1162, Dermod was the sovereign prince of Leinster. To great strength of body, he added a degree of courage and activity that rendered him formidable to the Ostmen, whom he defeated in battle, and kept within their own boundaries. Contemporarily with him was Roderic O'Connor, who was styled King of Ireland. It was not likely that two Irish chieftains should long continue at peace with each other. A cause of quarrel soon arose. In the district of Breffney, which consisted principally of the modern county of Leitrim, O'Roiark reigned; Dermod seduced, or ravished his wife; and, not content with this outrage, he also drove O'Roiark from his territories. The exiled prince sought the assistance of Roderick. The province of Leinster was invaded: The inhabitants, wearied and dispirited by the tyranny of Dermod, received the invader as their friend and liberator; and Dermod, in his turn, was compelled to flee from Leinster, and seek refuge in England.

At this period, Henry was unable himself to assist Dermod, or to invade Ireland; but he caused an edict to be issued in his favour, in which he stated that he had received Dermod under his protection, and promised the royal licence to such of his subjects as would aid him in the recovery of his territories. As soon as Dermod obtained this edict, he proceeded to the neighbourhood of Wales, both on account of keeping up an intercourse with Ireland, and because in Wales there were several of the nobility, who, from various causes, were most likely to assist him in his endeavours to be reinstated in his territories. In this expectation he was not deceived; for soon after the royal edict was read, and money and land were offered to those who would assist him, Richard, son of Gilbert de Clare, Earl of Strigul and Chepstow, engaged to come over to Ireland the following spring, on condition that he should receive in marriage Eva, the only daughter of Dermod, and with her the right of succession to all his property in Ireland. Other adventurers followed his example. Of these, the most famous was Robert Fitzstephen, a man who seems to have possessed most of the virtues, with but a small proportion of the vices of that age.

In A.D. 1169, Dermod returned to Ireland; and Fitzstephen landed in Ireland, in A.D. 1170. The first attempt of the united forces of Fitzstephen and Dermod was against this city, but they were repulsed by the inhabitants. The attack, however, was renewed the next morning by the English, and the inhabitants capitulated. Wexford was delivered up to Fitzstephen. Roderick alarmed at the success of these formidable strangers, and sensible of his inability to cope with them, concluded a treaty, by which Dermod regained the province of Leinster, on condition that he acknowledged Roderic as sovereign of Ireland. Dermod having thus attained his object, and having being reinforced by the arrival of some more English troops under Maurice Fitzgerald, marched to the attack of Dublin, the inhabitants of which he obliged to take the oath of allegiance. Strongbow or Strigul was still in England; but being called upon by Dermod to fulfil his engagement, he applied to King Henry, requesting either the restoration of his paternal property, of which he had been deprived, or liberty to seek his fortune in Ireland. To this application Henry gave an ambiguous answer; but Strongbow construed it to his own desire and advantage, and resolved to go to Ireland. Previous to his embarkation, however, he sent over a young man attached to his family, on...
whom he could depend, accompanied by 10 gentlemen of service, and 70 archers. In the meantime, Earl Strongbow was active in his preparations; and in August 1171, he landed in the bay of Waterford with about 200 gentlemen of service, and 1000 soldiers. Previous to his arrival, his forerunners had attempted to gain possession of this city; and though this did not succeed, yet they had greatly weakened its means of defence, so that it fell easily before the forces of Strongbow. As soon as this great enterprise was effected, and the promised marriage between Eva and the English chieftain solemnized, the allies marched towards Dublin, which seems to have revolted from the allegiance it had sworn to Dermot, and to have further roused his indignation and spirit of revenge, by having murdered his father. The inhabitants, intimidated and divided, were unable to defend the city, which soon and easily fell into the hands of Strongbow. The next object of the allies was the invasion of the territories of O'Loirik, Roderic O'Connor, alarmed at their progress, threatened to put to death the son of Dermot, who had been left with him as a hostage, if he did not desist from his purpose; and on Dermot's paying no attention to his message, he carried his threat into execution.

Meeting of the clergy.

At this period, the clergy of Ireland held a grand and general meeting at Armagh, to take into consideration the arrival of the English. At this meeting it was unanimously agreed, that "their sins, and particularly their custom of buying English subjects from pirates, and keeping them as slaves, had exposed them to the divine wrath:"

and it was therefore resolved, "that the English should be released from slavery, and henceforth that the practice of purchasing them should be abandoned."

As Henry was still unable, or disinclined, to invade Ireland himself, and as he was jealous, if not afraid, of the success of his subjects in that country, he issued a proclamation prohibiting any vessel laden with supplies from entering the ports of Ireland, and commanding all his subjects to return home, within a specified time, under the penalty of the forfeiture of their estates, and banishment. For some time the king refused to recall this proclamation, and, during this period, the affairs of the English in Ireland were in a precarious state. In 1171, Dermot died; and, in the same year, the Danes attempted to regain Dublin, but without success Obliged to be on his guard against the invasions of the Danes, and the intrigues and open wars of the Irish, Strongbow had continued and ample occasion for all his activity and presence of mind. As soon as the Irish princes were convinced that he had in vain applied to Henry to revoke his proclamation, they formed a confederacy against him, which was headed by Roderic O'Connor, and assisted by the king of the Isle of Man. This powerful body at the same time besieged Earl Strongbow and his troops, in the city of Dublin, and Fitzstephen and his troops, in a fort which he had built at Carreg. After much deliberation, it was resolved by Strongbow to sally forth from the city, and to direct their efforts against Roderic. This plan was executed with so much promptitude and silence, that the Irish were surprised and defeated; and Roderic himself escaped with difficulty. The city of Dublin and the province of Leinster being thus rendered secure, Strongbow marched to Wexford, near which the fort of Carreg was situated; but, before his arrival, Fitzstephen, alarmed by the report that Dublin was taken, had been induced to surrender himself to the enemy. Strongbow, however, marched forward. On his approach the Irish set fire to the city, and threatened to murder Fitzstephen and the rest of the prisoners, if he advanced farther.

Under these circumstances, and having received information that if he went to Henry himself, he might probably induce him to assist in the conquest of Ireland, he embarked for England. An agreement was at length settled between the king and him, the terms of which were, that the Earl should swear allegiance to the king; and give up to him the city of Dublin, with all the other cities and forts on the sea-coast; and, on the other hand, that the Earl should hold under the king the rest of his acquisitions in Ireland.

On the 18th of October, 1172, Henry landed at Waterford; his army consisted of 500 knights, and about 4000 troops; which were conveyed in 440 large ships. Soon after his landing, Fitzstephen was given up to him; and the kings of Cork and Limerick, as well as the princes of Osory and the Decies, voluntarily took the oaths of allegiance, and agreed to pay tribute. On his march to Dublin, other Irish princes followed his example; but Roderic O'Connor refused to come and offer his obedience to the English monarch; he, however, took the oath of allegiance before two of Henry's courtiers, who were sent into Connaught for that purpose.

Thus the whole of Ireland was nominally subject to Henry, but he was soon obliged to return to England, for the purpose of doing penance on account of the murder of Becket. Before his departure, he committed the custody of the principal cities and castles to the most trusty of his subjects, and took such other measures as he thought would at once serve to keep the Irish in awe and obedience, and would check the ascendency of Strongbow. But though these two objects seem to have been tolerably well secured, yet Henry could not guard against dissensions among his knights; two parties were formed, at the head of one was Raymond, already distinguished by his courage, enterprise, and success; and at the head of the other was Harvey. The former was so popular, as well as a man of such sound judgment, that it was deemed prudent to appoint him the general of the army, in order to appease their discontent, and to render them capable of resisting the Irish. In both these points he succeeded; for, being obliged to return into Wales, on the death of his father, the command devolved on Harvey, and a reverse of fortune speedily took place. The English were defeated in the neighbourhood of Cashel, by the Prince of Limeric; and Roderic O'Connor, crossing the Shannon, invaded Meath, and advanced to the very walls of Dublin. To add to their misfortunes, Strongbow was at this time besieged in Waterford. Raymond was again summoned; he obeyed the summons, relieved Waterford, and received Strongbow's sister in marriage. The next enterprise of Raymond was the relief of Leinster, which had been invaded by Roderic; but no sooner did the Irish prince hear of his approach, than he returned into Connaught.

Scurcly was this object accomplished, when the Prince of Limeric threw off his allegiance, and took up arms: Raymond marched against him; at first he found some difficulty in persuading his troops to cross the Shannon; but this being effected, the Irish were put to flight, and the city of Limeric occupied. These successes of Raymond, and his influence with the troops, were so represented to Henry by his rival Harvey, that,
IRELAND.

History.

he was ordered to return to Wales; and two councillors were sent by the king for that purpose; but they, as well as Strongbow, were so firmly convinced of the necessity of Raymond's continuance in Ireland, that his departure was put off, and he resumed the command of the army. His authority and talents were at this period of great service; for Limeric was invaded by his prince, who was assisted by a powerful chieftain of Kinsale. Against these Raymond marched, and having forced the pass of Cashel, the Irish princes were intimidated, and agreed to renew their oaths of allegiance.

From this part of Ireland the victorious general was recalled by the death of Strongbow; this event, and the necessity of his own departure for England, rendered it prudent to abandon the city of Limeric, as being at too great a distance from the principal seat of the English power. The troops were also withdrawn from the towns and forts of Leinster.

As soon as Henry was informed of the death of Strongbow, he appointed William Fitzzandelin to the chief command in Ireland. About the same time, a bull of Pope Adrian, constituting Henry its lord, was read before an assembly of the Irish clergy at Waterford. One of the first acts of the new governor was to render the situation of some of the original adventurers so uncomfortable, that they went in quest of new settlements: Hence were formed the settlement of Ulster by John de Courcy, and that of Connaught by Milo de Cogan. The expedition of the former succeeded, though not without much difficulty, and several obstinate battles with the Irish. De Cogan, on the contrary, was oblied to abandon his settlement.

As Ireland now began to assume the appearance of an important and valuable acquisition, Henry resolved to appoint one of his sons its feudal sovereign. Accordingly, in the year 1178, John, his youngest son, was declared lord of Ireland, in a council of barons and prelates; but he did not go to Ireland till the year 1185, when he was 18 years old. It soon appeared, that neither he nor his followers were qualified, either by their behaviour or intelligence, to reconcile or improve the Irish. The Norman courtiers mocked and insulted the uncouth garb and manners of the Irish lords, and increased the indignation thus raised, by seizing the lands of such of them as held under English lords by English tenure within the pale, that is, in those parts which had been colonized by the English. The fiery temper and high spirit of the Irish being thus roused, they flew into those parts of Ireland where they were most likely to gain assistance. The British possessions were invaded on all sides; so that, in less than a year, Henry found it necessary to recall his son, and appointed John de Courcy governor. The circumstances in which he was placed, would probably have rendered his efforts to retrieve the misconduct of his predecessor unavailing, had not the Irish princes quarrelled among themselves. Even then he was unable to take advantage of the death of Roderic, by gaining possession of Connaught; and it was not without great difficulty that he maintained the English settlements.

On the death of Henry in 1189, De Courcy was recalled, and Hugh de Lacey appointed in his stead. De Courcy, however, refused to obey the summons, and, retiring into Ulster, assumed the character of an independent chief. The Irish princes, as usual, roused themselves as soon as they found that their English rulers were divided among themselves; and, among these, Cathal, who succeeded Roderic in the government of Connought, was the most remarkable for his enterprise and success. The English government, weakened by dissensions, and by the sudden and repeated attacks of the Irish, was entrusted to different noblemen; but with no decisive or permanent amelioration. At length, in 1199, Fitzhenry, descended from a natural son of Henry I. of England, was appointed by John, who now filled the throne of that country, chief governor of Ireland. He was extremely well qualified for his situation; but, opposed by De Burgo, who held Limeric, he for some time was unable to carry into effect the plans he had formed for the tranquillity of Ireland, and the establishment of the English power. At last, in 1203, having succeeded in collecting an army of native Irish, he marched against De Burgo, and compelled him and his Irish allies to renew their allegiance. As soon as this was effected, Fitzhenry resolved to reduce De Courcy, who still maintained an independent authority in the province of Ulster, and refused to acknowledge King John. In this enterprise he also succeeded.

In 1210 John resolved to visit Ireland. His object is not clearly known; but the only event which he performed, during his stay of three months, was the reduction of the fortresses of Meath and Ulster, belonging to the Lacies, who had incurred his displeasure. In one most important point, however, the spirit of the English sovereign was highly beneficial to Ireland, for a regular code of English laws was promulgated; and, in order that these laws might not become a dead letter, through the want of proper and efficient means to carry them into execution, courts of judicature were established in Dublin. The territory which the English possessed was divided into counties, over which sheriffs and other civil officers were appointed. It does not clearly appear whether the English pale, as it was called, at this time comprised twelve or fifteen counties, though it is probable that there were only twelve, in Leinster, Munster, and Ulster; and that the three others, which lay in Connaught and the southern parts of Munster, were soon afterwards added.

The benefit thus conferred on Ireland by John, was followed by another still more important in the year 1216; for at this period Henry III. extended Magna Charta to Ireland. During the space of nearly 100 years, from that time, is, through the reigns of Henry III. and his successor Edward II. the history of Ireland presents a confused and interesting series of petty wars and amends among the Irish princes and chieftains, and the English lords. The English monarchs, occupied with more immediate and momentous concerns, had neither leisure nor inclination to attend effectually to the affairs of Ireland. One circumstance, however, demands and deserves our notice during this period. In 1295, the first regular Irish parliament was held; and, from their proceedings and acts, we may glean some curious and instructive information regarding the state of Ireland, and the causes of its domestic feuds; its ignorance, and barbarism. The defence of the English borders was entrusted to the lords of the marches; but they neglected their duty, living at a distance from the borders. The defence, and the improvement also, of the English settlements were weakened and impaired by the non-residence of many of the great proprietors; but the circumstance which probably most unequivocally the desperate state in which the English settlements were, and at the same time pointed out one of the principal and most deeply seated sources of the civil wars,
was the jealousy and ill-will that existed among the English themselves. Instead of uniting against the Irish whom they were attacked, they were sur-
plus and inattentive spectators of the attack, and seemed
rather to rejoice than to grieve at the misfor-
tune of their countrymen and neighbours. The con-
duct of many of the English lords was proved to be un-
just, both towards their own vassals and towards the Irish; the former they pressed down to the earth by exac-
tions the most oppressive, and the latter they fre-
quently attacked in defiance of the most solemn and
very recent treaties. Another proof that the English
settlements were retrograding into barbarism, existed
in the circumstance, that the English were gradually
assuming the dress and manners of the Irish, instead of
using their endeavours to raise the Irish in the scale of
nations, by introducing their own among them; and
the motive which thus led the English to assimilate them-
selves to the Irish, spoke still more decidedly in proof
of their degeneration, for they thus hoped to free them-
selves from the wholesome and necessary severity of
the English laws, by passing themselves off as native
Irish.

Such is the picture of Ireland, which the acts and
laws of the first regular parliament held there enables us
to draw; but it was almost impossible to administer
any sufficient remedy for the evils thus brought to
light. The English government, at that period, did not
possess either sufficient intelligence or sufficient power
to remove these evils; and, even when intelligent and
conscientious governors were appointed, they were so
much thwarted in their plans, by the open opposition,
or secret machinations of the English lords, and so
much occupied in defending the English settlements
from the attacks of the Irish, that they could effect lit-
tle or nothing, before the jealousy of the sovereign, or
the influence of some favourite, produced their recall.

In the mean time, the Irish were naturally anxious
to throw off the English yoke. They had beheld their
country, to which they were devotedly attached, be-
come the prey of foreign invaders, who, not content
with the conquest of great part of the island, seized
every opportunity to dispossess the Irish lords of their
possessions, and to oppress and destroy the common
people; and indeed, by every act, seemed to proceed on
a regular and fixed plan of repeopling the island with
English colonists. Towards the English, therefore, the
feelings of the Irish were very naturally extremely hos-
tile; but, to indulge these feelings with effect, to digest
any plan, and carry it into execution for expelling the
English, seemed beyond their power. They were di-
vided among themselves; and that strength which they
ought to have reserved and nourished, for the purpose
of pouring it down upon the common enemy, was al-
most destroyed.

For a long period of time there was no hope of as-
sistance from any foreign nation. At last, about the
beginning of the 14th century, their eyes were turned
towards Scotland, which country, from its hostile dis-
position towards England, in consequence of the inva-
sion of Edward I. they trusted would feel disposed to
assist them; and, from the decisive battle of Bannock-
burn, which it had gained against Edward II. they hop-
ed it would be able to render that assistance effectual.

As the north of Ireland, from its local situation, seemed
more naturally connected with Scotland than any other
part, so it first applied to that country for assistance.

Soon after the battle of Bannockburn, the Irish of Ul-
ster offered the sovereignty of Ireland to Robert Bruce,
if he would expel the English; this he declined; but
he sent his brother Edward with about 6000 troops to
the north of Ireland. Against such a force, joined as
they were by the Irish, breathing revenge, and acquaint-
ed with all the paths and resources of the country, the
English were totally unable to make any resistance.
The chief governor at this time was Lord Edmund
Butler. On him of course devolved the protection of
the English settlements; but, besides the army which
he collected, one was formed, and headed by Richard
de Burgo. The latter nobleman had long been jealous
of the chief governor, and the jealousy now broke out
to the prejudice of their own cause; for, though the
Earl of Ulster had accepted the assistance of the Irish
under Figgini, Prince of Connaught, he refused a rein-
forcement sent him by the governor. The effects of
this jealousy were soon apparent; for the Earl sustain-
ed a severe defeat from the Scotch, who were still lay-
ing waste the province over which he presided. As
Bruce was sensible, that without the co-operation of
the Irish he would be totally unable to keep his ground, and
as he had reason to believe that Figgini might easily be
detached from the cause of the English, he turned all
his thoughts to effect this object; and, at the same time,
carried on a secret negotiation with Roderic, who had
claims on the province of Connaught. As soon as Fedge
lim learnt that Roderic was endeavouring to take ad-
vantage of his absence, he left the English, and return-
ed to Connaught; and his rival being slain in an en-
gagement, he then openly deserted his allies, and turn-
ed his arms against them. At this circumstance might
have had a fatal effect on the cause of the English, a
strong force was sent against him, and, after a most de-
perate resistance, he himself was killed, and his army
completely routed, at the battle of Athenree, in the A. D. 1316,
year 1816.

The deflection of Figgini from the English cause, was
followed by that of several other Irish princes; so that
the Scotch were enabled to march from the north towards
Dublin; and having reduced the strong fortress of Car-
rickfergus, they invested the capital. But though Ed-
ward’s army was now still further increased by a body of
troops which his brother Robert brought from Scotland,
and by the junction even of some English families of
distinction, yet he found himself unable to make any
impression upon Dublin; and at the same time, he learnt
that very formidable measures were taking to arrest his
further progress. In fact, an army amounting to nearly
30,000 troops, most of them indeed ill disciplined and
ill equipped, was assembled at Kilkeny, and a new
 governor, Roger Mortimer, was sent over. Retreat
now became absolutely necessary; but Ulster, into
which the Scotch retreated, having been utterly devas-
tated by them on their first landing, could not support
them; famine and pestilence attacked them so dread-
fully, that they were soon greatly reduced in numbers.
The new governor resolved to take advantage of this
circumstance; but he did not entrust the attack to the
rabble assembled at Kilkeny. A regular army of
1600 men, under Sir John de Birmingham, was sent
against the Scotch, whom, though nearly double their
numbers, they defeated with great slaughter at Dundalk
and Dun-
in 1318. In this battle Edward Bruce was slain. The
English government, after this great effort to preser-
vise their Irish territories, seem to have relapsed into
their accustomed indifference about them; and the usual
consequences followed. Instead of the native Irish be-
ing stimulated or guided towards improvement by the
English, the latter in great numbers renounced the
name, character, and privileges of English subjects; the English troops, unpaid and undisciplined, were permitted, and even ordered to levy exactions, to supply the place of their pay; and this they did with so much capacity and cruelty, that the settlements in the south, over which, as at the greatest distance from the seat of government, they tyrannized in the most dreadful manner, were deserted by the English, and occupied by a horde of lawless and savage banditti, over whom even some of the English lords placed themselves, with the title of Irish princes. These princes were constantly at war either with one another, or with the English; but the circumstances of these petty warraies are too uninteresting for detail.

Ireland, thus reduced to a state of barbarism, and its constant attendants misery and poverty, was doomed to suffer still more from the unjust, as well as impolitic measures of Edward III. This prince, impoverished by his wars with France, resolved to draw money from Ireland, by the only mode in which it was capable of supplying it. With this view, he resumed all grants of estates made by himself or his father; and declared, that none except Englishmen, who possessed property in Ireland, should hold land in the south. The sudden measure naturally excited deep and general alarm, while, at the same time, it as naturally gave rise to two parties or factions, viz. those that were English by birth, and those who were English only by blood. Edward probably was soon sensible of his error, for he returned a gracious and favourable answer to the representations of the parliament on the subject of his ordinances, and at the same time promised a redress of the grievances which they enumerated.

As a repetition of the disturbances and petty rebellions by which the history of Ireland is at this period, and for some time afterwards, principally distinguished, would be tiresome and uninteresting, we shall pass them over, and select only such circumstances and transactions as tended to improve the condition of this country; these, unfortunately, have always been few, and "far between;" and, till within a very recent period indeed, rather deviations from, than in strict conformity with, the principles on which the English had ruled over Ireland. The great measure of domestic politics, that of Ireland, was, at the same time, of the utmost importance, being intended to promote the security of the people, and to prevent the recurrence of the wars and disturbances to which the kindred and unnatural hatreds of the inhabitants were given occasion. The efforts of the government in this direction were, however, impeded by the jealousy of the English, who resented with all their might every attempt at conciliation. But, in the reign of Henry IV., the difficulty of conciling the English and Irish by any mode short of force, was removed by the success of an intrigue in which Poictiers, the French king, was confederated with the Irishmen to effect the conquest of the diocese of Cashel. From this time forward, the name of the French king was heard in Ireland, under the title of "king of the French and Irish nations," and the government of Ireland became a matter of contention between the English crown and the French king. This double sovereignty, however, proved of short duration; for the French court, finding that the English and Irish were equally desirous of its destruction, abandoned the project, and the King of England restored the original constitution of the state, with all its defects, and free from the intrigues of the foreign court.

In 1356, Ireland was favoured with a wise, humane, and just governor, Sir Thomas Rokey; his favourite saying was, "let my dishes be wooden, rather than my creditors unpaid." Convinced that no good could be done to Ireland, which did not proceed from the highest source, and that the mass of the people must remain barbarous and unrestrained by law, so long as the higher orders were so, his first steps were to improve the latter. He brought the Irish parliament as nearly as possible to the model of the English, and when, by this means, he could depend upon their judgment and impartiality, he assigned to it the decision of all appeals from inferior courts; these had been carried heretofore into England. He thus lessened the expense and trouble of law-suits, while at the same time he habituated the Irish to a knowledge of law, and by putting confidence in them, rendered them worthy of confidence. Unfortunately, however, the wise measures of the chief governor were counteracted by the unjust and impolitic proceedings of the king; he forbade any more Irishmen from being admitted into any office or place of trust, in any city, borough, or castle, or into any ecclesiastical benefice; thus proclaiming his suspicions of the Irish, without doing any thing to remove their dislike of the English. Finding this
IRELAND.

History.

receiving revenues from the colonists, protected them from their own countrymen.

In the civil wars of the houses of York and Lancaster, the English in Ireland took a decided part. The most powerful families were the Geraldines of Desmond and Kildare, and the Butlers or O'Byrnes. The former adhered to the house of York, and the latter to the house of Lancaster. Soon after the accession of Edward IV, the power, influence, and property of the Butlers were greatly reduced by the Irish parliament, while the Geraldine faction increased in influence. In the year 1468, Thomas, who was the head of this faction, was appointed lord deputy; but he was rash and ill advised enough, to march into Meath against the Irish chieftains, where his army was defeated, and himself made prisoner; but afterwards liberated, through the affection and gratitude of an Irish chieftain. This reverse, however, had rendered him unpopular at the English court, by which he was deprived of his government, and afterwards beheaded, on the plea that he had contravened the statute of Kilkeney against forming connections with the Irish. The Earl of Kildare was accused at the same time of the same criminal act. Being sent into England, he not only obtained his pardon from the King, but also the appointment of lord deputy.

In the midst of these events, the English settlements were still feeble and ill protected; and at last in 1474, a fraternity of arms was instituted by act of parliament. This fraternity was composed of thirteen of the most powerful and well disposed persons in that district, which was more immediately and completely under the dominion of the English, viz. the counties of Dublin, Meath, Louth, and Kildare. By these persons was to be elected annually a captain, under whose command were placed 120 archers on horseback, and 40 other horsemen, besides one person to attend on each. Thus a force of 213 men (for the fraternity were themselves to act as soldiers) was raised; but it is evident, that this small force was inadequate to the defence of the extensive borders of the English settlements, and even to the preservation of tranquillity within their settlements. In fact, the security of the English in their possessions, was regularly purchased by a tribute to the Irish chieftains. The pay assigned to each archer raised by the fraternity was sixpence per day, and fivepence to each other horseman with his attendant. The sum necessary for this purpose was supplied by taxes, and, though to a trifling amount, they were levied with great difficulty. The family of the Butlers, though greatly reduced in numbers and in power, was not annihilated; and the chief surviving member, by his address, obtained from the King the reversion of the act of attainder, and the removal of the Earl of Kildare from the office of lord deputy. For some years there was a struggle between the Geraldines and the Butlers for the King's favour. At last, in 1478, Gerald Earl of Kildare was appointed deputy. Scurrely, however, had he obtained this office, when he was superseded by Lord Grey. Against this appointment he remonstrated with such effect, that he was reinstated in his office, the duties of which he performed with great prudence and address, till some years after Henry VII. ascended the throne of England. His being continued deputy by this monarch, who must have been prejudiced against him, as an adherent of the house of York, may partly be ascribed to Henry's apprehension of disturbances while he was yet unsettled on his throne; but it probably also arose, in part, from his sense of the good conduct of Kildare. This nobleman, however, soon afterwards swerved from the line of conduct he had hitherto pursued, and Henry's suspicions were excited against him, and his Irish subjects in general, among whom the cause of the house of York had always been popular. They then hastened to this cause they openly manifested, by the encouragement they gave to Lambert Simnel. This impostor was sent, by those who supported him, to Ireland, where he was proclaimed by the lord-deputy and the council by the title of Edward VI. Having thus committed themselves, they prepared to uphold the cause which they had espoused; and the Yorkists in England gladly co-operated with them; besides English troops, 2000 Germans were sent by the Duchess of Burgundy, sister to Edward IV. into Ireland, in the hopes that they would draw Henry into that country, and thus leave England open to the operations of the Yorkists. But not succeeding in this, the army was sent over to England. Before their arrival, however, the imposture of Simnel had been detected, and the people received them everywhere as foes than as allies or friends. They still, however, pushed on, and, as Henry was also advancing against them from London, the hostile armies met at Stoke, in Nottinghamshire, on the 6th of June 1487. The battle was long and obstinate, but at length terminated in the complete victory of the king. Henry, with his usual prudence, which always with him was superior to mere feeling, pardoned, with scarcely one exception, the supporters of Simnel.

The state of Ireland, at this period, presents the same picture of intrigue, domestic feuds, and poverty, which we so frequently have had occasion to exhibit before. Henry seems to have been fully sensible, that territories in this state could be no source of power or revenue to the monarch, but must rather tend to weaken and distract those parts of his dominions which were in a sounder and quieter condition: but it was very difficult, in the first place, to detect the causes of this state of Ireland; and it would have been still more difficult, had the causes been detected, to have removed them by the effectual application of the proper remedy.

After much inquiry and deliberation, Sir Edward Poyning was appointed lord-deputy, with instructions to probe the evil thoroughly, and to direct his whole thoughts to its removal; and, in order that his measures might be properly executed, and well supported, he was attended by 1000 soldiers, and by a number of English, who were qualified to fill the offices of lord chancellor, lord treasurer, and judges in criminal and civil causes. His administration is particularly remarkable for the acts passed by the Irish parliament, called after him Poyning's Acts.

Some of these acts were evidently calculated and intended to repress the power of the barons, and to prevent the recurrence of their mutual quarrels. For this purpose they were forbidden to have any followers, except their household officers and servants; and even the lords of the marches, who necessarily had a large retinue, were obliged to give in the names of their attendants. In order that the sheriffs should execute their duties with effect and impartiality, they were to be henceforward appointed by the lord treasurer. None but those of English birth were to command in the forts and other strong places. These enactments were calculated to preserve tranquillity among the barons, and, if possible, to insure their fidelity; but there were also enactments, the object of which was to relieve the mass of the people from the oppressions under which they
loured; by levying the taxes in a more equal manner, and by protecting the people from the exactions of their lords and the military. But the act which is more generally and particularly known by the name of Poyning's Act, was of a different description from those first described; by this act, it was provided that no parliament should be held in Ireland, without previously stating to the king the reasons on account of which it was to be summoned, and the laws which it was intended to enact. Whatever might have been the necessity, the expediency, or the benefit of such an act, at the time it was passed, it is evident that it rendered the parliament of Ireland a mere mockery, while it enabled the English sovereign to enslave and tyrannize over the Irish, as well as to keep them back in civilization and resources by means of their own parliament. Just before Poyning returned to England, he had an opportunity of crushing the power of the Yorkists, the chief, the Earl of Kildare, having imprudently joined the adventurer Warbeck in Munster, and on his defeat having been taken prisoner. Henry, however, had penetration enough to discover, that if he could make Kildare his friend, no man was so well qualified to govern Ireland in tranquillity; and if Kildare seemed disposed to attach himself to the king, and on his trial repelled the charges against him in a satisfactory manner, the king appointed him governor of Ireland. The great objects which Kildare had in view, were the external defence and the internal tranquillity of the English settlements: The former he succeeded in effecting, and, indeed, rendered these settlements more secure than they had been for a very long period; but his attempts to conciliate the Butlers were unsuccessful, though he succeeded so far as to form a matrimonial connection with that family. Still farther to increase his own influence, he married his daughter to the Lord of Clanricard, who was the head of a large number of those English who had assumed the manners, the language, and the dress of the Irish; but this marriage proved unfortunate, for such an inveterate quarrel arose between the earl and his son-in-law, that open and regular hostilities took place between them; each party strengthened themselves by alliances, so that, from a petty dispute, it increased to a civil war. The Irish Prince of Connaught, the O'Briens of Thomond, and in general the chiefs of Munster, ranged themselves on the side of the Lord of Clanricard. On the side of the governor were the English barons, the O'Neills, and some other chiefs of the northern provinces. The hostile armies met at Knocktow, near Galway, on the 19th of August, 1504. The forces of Clanricard were much superior in respect to numbers; but in discipline, skill, and steadiness, they were far inferior; their first attack was very impetuous; but that being received with coolness and firmness by the archers in the governor's army, the assailants gave way, and in the confusion with which they fled, upwards of 2000 were slain. Kildare continued governor till his death in 1513; at this period Henry VIII. was on the English throne, and, occupied with various schemes of vanity and ambition, the affairs of the English settlements in Ireland were so little attended to, that on the death of Kildare they relapsed into their former disorder and weakness, and would probably have become much worse, had not Gerald, the son of Kildare, been appointed governor. He was, however, by no means equal in talent to his father; and the Butlers resolved to seize this opportunity of ruining the Geraldines, and recovering their former power and influence. At the head of this family was Peter Butler, who had married a Geraldine; but this woman, so far from feeling any family attachment to her blood relations, stimulated her husband against them. Butler succeeded so far as to procure the removal of Kildare; but it does not appear that he immediately benefited himself much by it, for Howard Earl of Surrey was appointed Lord Lieutenant of Ireland in the year 1520. Howard's administration lasted two years, and was principally occupied in reducing such of the Irish chieftains, as from their vice and hostile dispositions were most formidable to the tranquillity of the English pale. In this object, as well as in his other plans, which were judicious and prudent, he most probably would have completely succeeded, had he been promptly and properly supported by his sovereign; but this not being the case, he requested to be recalled, and his request was complied with. For a short time Butler now engrossed the power which he had long coveted, but he was supplanted by Kildare, who, by his powerful family connections in England, and by his flattery of Henry, was reinstated in the office of governor. Again he fell under the displeasure and suspicion of the king, and was deprived of his situation, because he did not obey the commands which were given him, to seize the person of the Earl of Desmond, who had, at the instigation of Francis the First, agreed to take up arms against Henry. This fact deserves notice, as it presents the first instance of that policy of the French, which has so often subsequently led them to rouse the Irish against the English. Perhaps in no respect was the instability of Henry more conspicuous, than in the rapid and extreme changes which he effected in the government of Ireland; for, soon after Kildare was a third time appointed governor, he was succeeded by Butler. The consequences were such as might have been anticipated: vacillating councils, imbecile proceedings and measures, and an increase of the family hatred which had so long existed between the Geraldines and the Butlers. At length Kildare, who was then governor, being Kildare's order to repair before the king to answer the charges rebellion. Against him, prepared his plans before his departure, A.D. 1523, for open rebellion, and committed the government to his son Thomas. This young man, rash and violent in his temper, was too well disposed to second the views and schemes of his father; and a rumour being spread that he was put to death by Henry, the son immediately embarked in open and avowed rebellion. His movements were rapid and bold; he first marched to the attack of Dublin, but he was unequal to the reduction of this city; he was more successful against the Butlers, defeating their troops, and laying waste their country, on their refusal to unite with him. Elated with his success, he prevented for some time the landing of the English forces, but being obliged to retreat, and the winter setting in, he spent this season in recruiting his forces in the west of Ireland. The next year witnessed the termination of this rebellion; for his troops were so disconcerted and alarmed at the reduction of the castle of Maynooth, that they either deserted or fled in confusion on the approach of the English. Lord Thomas immediately surrendered himself on promise of a pardon, which, however, was not performed, for he and his five uncles were executed. As his father had previously died, only one of the Kildare family remained, a brother of Thomas, about
twelve years old, who was secretly conveyed into the Netherlands out of the reach of Henry's vengeance.

Lord Grey, who was appointed deputy, met with few difficulties or obstacles from the Irish chieftains, but the Butlers were still active in intrigue, and it was deemed necessary to accept their professed allegiance, though their actions were by no means accordant with it. It was not, however, to be expected that the Irish chieftains would long remain tranquil. At the head of those of the north was O'Neil, formidable for his own power, and for the influence which he possessed. Suddenly, in the year 1539, he advanced into the neighbourhood of Dublin, but, on the approach of the Lord Deputy's forces, he retreated with his booty till he reached the borders of Meath. Here, strongly posted, with a river on his front, he awaited the issue of a battle, at Bellamoe. Lord Grey immediately crossed and attacked the enemy, who, after a slight resistance, fled in all directions. Grey, however, did not live to witness the fruits of his victory, which were sufficiently manifested by the submission of the chieftains, even after his death. So complete was this submission, that Henry, in 1541, received from the Irish parliament the title of king of Ireland, instead of lord.

To reward the chieftains for their submission, and to keep them faithful, O'Neil was created Earl of Tyrone, O'Brien Earl of Thomond, and De Burgo Earl of Clanricard.

At this period, when after many unsuccessful attempts, it seemed probable that Ireland would subside into a state of comparative tranquillity and civilization, a new source of civil warfare, of hatred of the English, and of devastation arose. We allude to the attempts which were made to convert the Irish to the Protestant religion, and the sturdy consistency which the great majority of the Irish displayed in adhering to the old religion. The means that were adopted by Henry VIII. and his son Edward, to introduce the Reformation, were extremely inconsiderable; and as it was strenuously opposed by the primates, it made scarcely any progress, when the accession of Mary destroyed the little of it that had taken root. But though this queen, on account of her religion, was a favourite with the Irish, yet they did not display their attachment by remaining perfectly quiet during her reign; on the contrary, such a formidable insurrection broke out in the districts of Leix and Offally, that, when it was quelled, it was judged necessary to vest them in the house, and to place them under the jurisdiction of sheriffs; the name of Leix was changed to that of Queen's County, and of Offaly to King's County. The same parliament which passed these enactments in 1557, passed an act explanatory of Voyning's law, by which it was declared that no bill nor even the heads of a bill, should be framed by the lords or commons of Ireland, but only by the viceroy and his council, or by the king and his council; and that the bill thus framed was to be passed into a law by the Irish parliament, or rejected without alteration or debate.

During the latter part of the reign of Mary, the north of Ireland was agitated by the machinations of O'Neil, and the south by the turbulence of O'Brien. On the accession of Elizabeth, O'Neil having made his peace with the earl of Kildare, repaired to London, where he was graciously received by the queen. His submission, however, was short and insincere; for as soon as he had assembled his forces, he appeared openly in arms, while, at the same time, he had recourse to intrigue. But at neither availed him, and he saw himself surrounded by the royal troops and their Irish auxiliaries, while he was deserted by a large portion of his army, he surrendered himself to a body of Scotch who had landed in Ulster, by whom he was assassinated in 1567.

The disputes between the Geraldines and the Butlers still continued; and, in an attempt made by the Earl of Desmond to seize some lands of the latter, he was surrounded, taken prisoner, and sent to England; from which he was sent back to Dublin. His party, in the mean time, rose in rebellion. This induced him to attempt his escape, which he effected; but he deemed it prudent not to join the rebels at first. His intentions, however, being suspected, he was attacked as an enemy, and reduced to the most abject state of misery, so that at length he implorcd, as an act of mercy, that he might be sent a prisoner to London, but in vain. Under these circumstances, hope revived in his breast at the intelligence of the arrival of a body of Spanish and Italian forces, with a large quantity of arms. This hope was not of long continuance, for the foreigners were defeated, and being deemed freebooters, were massacred by the command of the lord deputy. The Earl of Desmond was thus compelled to hide himself in the most unsuspected places; but even here he was not safe, for he was discovered by an Irishman, who cut off his head, and brought it to the Earl of Ormond.

Civil wars in all countries are carried on with the utmost violence and cruelty; and in the state in which Ireland was at this time, this civil war, or rebellion, as it is generally styled, was rendered horrible, especially in Munster, by every species of cruelty, the features and effects of which were heightened by famine. Elizabeth at length directed that sagacity and policy to the affairs of Ireland, which she had too long withheld from them; and, in 1584, Sir John Perrot was appointed lord deputy; for the high and arduous duties of his situation he was amply qualified, both by experience and by talents and disposition. His plan was simple, but could it have been carried into effect, it would have been decisively and permanently advantageous. He first visited those parts of the country which had always been the scene of the most violent disturbances, and this journey having convinced him that the plan which he meditated was well calculated to produce the effects he wished, he resolved, without loss of time, to put it into execution. It consisted in the gradual introduction of the English law, administered with impartiality and steadiness, into all parts of Ireland. This ought to have been done before; but it had not; and Perrot, much to his chagrin and disappointment, soon found that the English government were not disposed to furnish him with the means of carrying it out. Besides this source of disappointment, another awaited him, in the proceedings of the parliament, which strenuously set themselves against him, solely because he wished to act according to law, justice, and sound policy towards the native Irish. Perrot, however, still persevered, and did as much good as he could with his limited means, and under the prejudice and opposition by which he was encountered. To these sources of disquietude others were added, for disturbances broke out in Connaught and Ulster; but such was the influence of his character, that, before his departure, the suspected Irish chieftains obeyed his summons, and gave hostages for their fidelity; and his successor, Fitzwilliam, found Ireland tranquil when he assumed the government.
IRELAND.

That it should remain so, was a matter of serious moment to Elizabeth, for the Spanish armada was at this time at sea, and the Irish, it might justly be apprehended, would rise up in arms, unless prudently managed, if the Spaniards were even reported to have succeeded in their object. These considerations, however, did not weigh with Fitzwilliam; and on the contrary, by his conduct he exasperated even those Irish chieftains who were well disposed to the English.

The disaffected chieftains gladly seized the opportunity which this mal-administration presented, of forwarding their views. At the head of them, in the north, was Hugh O'Nei]l, than whom, few persons were better qualified at once to rouse and direct the Irish, and to offer a steady and dangerous opposition to the English. But though his designs had been long formed, yet he contrived, by his caution, and apparent devotion to the English cause, to elude their suspicions; and when they were raised, to remove them, more than once, before circumstances in a manner forced him to undisguised rebellion. Before this event took place, disturbances broke out in Connaught, headed by one O'Donnell, a Scotch adventurer, which distracted the attention, and divided the forces of the English. O'Nei]l carried his dissimulation so far as even to attack O'Donnell; and though he relied greatly on some Spanish forces which he knew were to be sent into Ireland, yet he also sent the letter announcing the promise of these forces from the Spanish king, to the Lord Deputy and council. But while he was thus, to all appearance, acting the part of a loyal subject, he was exerting all his endeavours to render his rebellion, when he should deem it prudent, or be forced to engage in it, more formidable and general.

As his character and schemes were known, though the behaviour of the English government towards him was not so decided and firm as it ought to have been with this knowledge, it was deemed proper to send a new deputy. Thomas Lord Burgh was appointed to this situation. His actions displayed immediately his just sense of the state of Ireland, and of the real views of O'Nei]l; without loss of time, he attacked him in his strong camp near Armagh, drove him from it, and afterwards defeated him a second time. Unfortunately De Burgh died in the midst of his victories, and O'Nei]l took advantage of this and other circumstances, and managed with so much adroitness, as to obtain from the queen a pardon under the great seal.

He sought, however, only a breathing time; and having, during this, recruited his forces, he again took up arms. His first engagement being successful, the royal army being routed, and the fort of Blackwater having surrendered, nearly the whole of Ireland, encouraged by these events, burst into open rebellion. Elizabeth was at last alarmed; but unfortunately, her partiality for Essex induced her to send him over as lord lieutenant. But he was not equal to his situation; so that while the royal forces in different parts were defeated by the rebels, Essex himself was so completely deceived by O'Nei]l, as to grant him a truce for six weeks. Soon afterwards, Essex left Ireland, and O'Nei]l renewed the war, having called in the powerful aid of religion to extend and support his cause.

Blunt, Lord Mountjoy, was next appointed to cope with O'Nei]l, who at first affected to despise him on account of his character for literature; but Blunt soon convinced him, that sagacity was more than a match for cunning; and by his rapid and successful movements so disconcerted O'Nei]l, and lowered him in the opinion of his confederates, that they began to exhibit symptoms of declining zeal and confidence.

The south of Ireland was, at the same time, the scene of nearly equally judicious and successful measures, adopted and pursued by Sir George Carew, who commanded the Queen's forces there. Sensible that he could not act with any prospect of success against the united Irish chieftains, and well acquainted with their jealousies and suspicions of one another, he turned these jealousies and suspicions to his own advantage; and having thus disunited the enemy, he carried on his military operations with vigour and success.

Hitherto the King of Spain had withheld the assistance which he had promised; but at length, in September 1601, about 6000 men landed at Kinsale. Against these Blunt marched, and blocked them up in that town. As soon as the landing of the Spaniards was known to the rebel chiefs, O'Donnell moved to join them from Connaught and Leinster, and O'Nei]l from the north. Thus the fate of Ireland seemed to be brought to a point: On the one hand were the forces of the Spaniards, which had been augmented by 2000 men, and the armies of O'Donnell and O'Nei]l; on the other were the forces of the Queen, under the Deputy, O'Donnell, with the Spaniards that had last landed, and O'Nei]l with his troops, took up such a position as to cut off the Deputy's forces on the land side, while by sea their supplies were very irregular and insufficient. The consequence was, that the royal army was gradually reduced in numbers and spirit, and must have fallen before the continued blockade of its enemies; but they were divided in opinion, and O'Nei]l reluctantly gave way to the opinion of those who advised an attack. As soon as Blunt saw them advance, he also left his entrenchments; and while Carew, with part of the forces, continued the siege, he himself, with only 1200 infantry and 400 cavalry, resolved to meet the enemy, who were very far superior in numbers. On this occasion, the advantage of talent over mere personal bravery was evident. The Irish, first intimidated by the boldness of the measure adopted by Blunt, and afterwards perplexed by his judicious disposition of his forces, displayed symptoms of indecision. Of these Blunt immediately took advantage, and the enemy were defeated in a very short time, and with very little loss on the part of Blunt. The effects of this victory were most important: Kinsale surrendered; O'Nei]l was deserted by his own adherents; and he submitted, almost at the very moment of the Queen's death. Thus Elizabeth lived just long enough to effect the subjugation of Ireland, a measure which had been attempted in vain by her predecessors.

In the reign of James I. there were some disturbances in Ireland, partly of a political and partly of a religious nature; but they were so uninteresting, and so unimportant in their consequences, that we shall pass them by, and advert only to such measures and transactions as relate to the internal policy of this country. Before Blunt left Ireland, he freed the Irish peasantry from the tyranny of their chiefs, and ordered them to be considered and treated as the immediate vassals of the crown. His successors seem to have been animated with the same spirit of conciliation, and to have imbibed his views; and, fortunately, James either approved, or at least did not oppose their measures: circuit judges were appointed; the law was administered with impartiality; the right to landed property was rendered more secure, and more conformable to justice; such lands as were held under the great lords had a fixed rent put
IRELAND.

The English government next turned its attention to the colonisation of the immense possessions which were forfeited; nearly 800,000 acres were in this predilection in the north of Ireland; and these it was resolved to settle with such people, and in such a manner, as might render the colonisation beneficial both to the settlers themselves and to the Irish. As this desire was sincere, and as the plan was thoroughly digested by able and impartial men, the object was accomplished in a much greater degree than might have been anticipated.

In 1613, the first national parliament was held in Ireland. Their first proceedings were tumultuous; but afterwards they conducted themselves with more decorum, and their acts were wise and beneficial. O'Neil, who had again embarked in treasonable designs, but afterwards fled to the continent—the Earl of Tyronnel, who had joined him—and O'Dogherty, who had been concerned in an Insurrection, were attainted; amnesties and pardons were granted to all others. The measures of the king to abolish the distinctions between the English by birth, and the English by blood, and to place the entire Irish under the protection of the law, were approved by the legislature; and the session was closed by a bill of subsidy.

Notwithstanding these judicious measures, and the apparent tranquillity of Ireland, there still existed serious causes of dissatisfaction; but these had now assumed a religious character. The Reformations had made little progress—the great portion of the nobility, and nearly all the lower orders, were still attached to the Catholic religion; and as they were cut off from the possession of offices by their refusal to take the oath of supremacy, there were thus implanted in them two weighty reasons of discontent—difference of religion, and the disabilities which this occasioned. But, as they were sensible of their own numbers and power, they openly urged their claims and wishes, and opposed the measures of the Protestants. From this source had arisen the tumultuous proceedings of the parliament when it first opened; and the dispositions displayed by the recusants (as they were called) to make demands in religious matters, caused its unexpected dissolution. The pope naturally approved and supported the measures of the recusants; and, in order that they might hold together, and act with decision, he appointed a regular hierarchy throughout the kingdom, all the members of which met with as much respect and obedience as they had received when the Catholic was the established religion.

Such was the state of Ireland when Charles I. ascended the throne. In 1633, that monarch appointed Wentworth lord-lieutenant. He entered upon his office with notions that were by no means calculated to render him popular, or to benefit Ireland: for he carried his ideas of the right of conquest to the utmost extreme; and acted on these ideas, both in his general administration of the country, and in his treatment of individuals. He seems, however, in some respects, to have benefited Ireland; for though he discouraged the woolen manufacture, because it might injure that manufacture in England, yet he gave his countenance to the establishment of a linen manufacture in Ulster. In 1610, Wentworth left Ireland, to assist his royal master in the difficulties and troubles in which he was involved, having previously, as he thought, proved and secured the loyalty of the Irish parliament. As soon, however, as they found that Charles was involved in a war with Scotland, and that the English parliament were rising in their demands from him, they forgot their protestations and promises, and directed a remonstrance to be sent to the king regarding the grievances they had suffered from Wentworth. This remonstrance, instead of being presented to his majesty, was communicated to the English House of Commons, who naturally fomented and encouraged the discontent of the Irish. The king, under these circumstances, was obliged to yield, and to agree that most of the grievances complained of should be removed. This concession only stipulated to fresh demands; and, to render these demands more imperative, the recusants and puritans, who formed the majority of the parliament, united.

It is not to be supposed that the Irish chieftains were inactive during this state of things; on the contrary, they used their utmost endeavours to persuade the people, that the moment was arrived when they might shake off the English yoke. The most active and enterprising person on this occasion was Roger Moore, whose rebellion.

The levying of troops for the Spanish service had been very injudiciously permitted in Ireland: these troops were kept in the country by the contrivance of Moore and his associates, who also increased their numbers. Upon these Moore mainly depended for setting the rebellion in motion; and he trusted that his measures were so well taken, that, when once set in motion, it would spread rapidly over the whole kingdom. The first object was the seizure of Dublin castle. Attempts to seize it were made on the 22d of October 1641, by Moore and his associates, as the centre of the capital, with an intention the next day to attempt the seizure; but on the previous evening the plot was discovered to the lords justices. This part of the scheme of Moore was of course frustrated; but his associates in Ulster rose in such strength, and so simultaneously, that in the course of a very few days they were in possession of nearly the whole of this part of Ireland. The Protestants, alarmed, and completely taken by surprise, fled to their strong places. As soon, however, as they had digested their plans, and recovered from their alarm, they marched out against the insurgents, whom they defeated and checked in many parts. This served only to enrage them, and the hostilities they carried on soon began to assume all the horrors of civil war, such as it is always waged where religious bigotry sharpens the edge of political hatred, and where they both act on savage and barbarous dispositions. The most cruel and unexampled of massacres were committed by the rebels; by the remorse was the conduct of their opponents sustained by acts nearly as atrocious.

Charles was totally unable to subdue the insurrection, and the English parliament did not deem it poli-
Hitherto the Catholics of the pale had refused to join the insurgents; but, being left unprotected, and thus exposed to their ravages and contributions, they wavered in their allegiance, and were at length decided in their resolution to join them, in consequence of a victory they obtained over the royal forces near Drogheda. Had the administration of Ireland, at this period, been conducted by men sincere in their attachment to government, and of moderate capacity and activity, the rebellion might have been quelled, even after it had spread thus far, and taken such deep root; but neither the civil nor the military measures of the lords justices were of such a nature as the exigencies of the times required. The force which they possessed was weakened, and rendered less effectual, by proper and instant attacks on the subordinate and distant forces of the rebels, instead of being brought to bear, in one body, on their most vulnerable points. The soldiers were thus harassed and dispirited, while Moore and his associates gained strength and spirits daily. Even Dublin was threatened by them; and it is probable that they might have taken it, if they had not delayed their march, and laid siege to Drogheda. Against this place they were unsuccessful, in consequence of the approach of Ormond, who would have prosecuted his success had he been allowed by the lords justices.

As soon as the Catholics of the pale received intelligence of the success of Ormond, they offered to desert the cause of the rebels, which they had reluctantly joined, and to which they had never been sincerely attached; but they were not received by the lords justices as sincere in their wishes. On the contrary, they were prosecuted with the utmost violence, it is supposed with a view to render the forfeiture of lands more extensive; and, in this plan, they encouraged the English House of Commons, who looked forward to the sale of the forfeited lands, as the means of enabling them to prosecute the war against the king. Thus driven to despair, the Catholics of the pale were forced to violent measures; and, having formed an army of 8000 foot, and some troops of horse, they attacked Ormond near Kilkenny; but though superior, they were not able to make any impression on his better disciplined troops, and the contest ended in their precipitate retreat.

This defeat saved the city of Cork, which had been besieged by the insurgents of Munster; for, during the dismay which it occasioned, being attacked by the garrison, they also were routed. The consequences of these defeats of the rebels, however, were not nearly so advantageous as they might have been, if the royal armies had been properly supported. The rebels also, about this period, were still further excited against the English by the fanaticism of Hugh Peters, who accompanied Lord Forbes; a general appointed by the parliament.

The English House of Commons at last became sensible of the necessity of taking vigorous measures for the reduction of the rebels; and accordingly they concluded a treaty with the Scotch parliament, by which the latter agreed to send 10,000 men into Ulster; but these troops were more active in plundering the country, and exporting the cattle to Scotland, than in pursuing the rebels. The English forces, therefore, in this part of Ireland, were obliged to trust entirely to their own unassisted efforts; the first success of which seemed to open up the prospect of more permanent and decisive advantages, when the arrival of Owen O'Neill from Dunkirk, with 100 officers; and a large supply of arms and ammunition, directed their attention to the necessity of checking him.* In this enterprise they were again disappointed, in not being assisted by the Scotch, though the Earl of Leven, their commander, was now at the head of 20,000 foot and 1000 cavalry; but, instead of acting, he contented himself with sending a message to O'Neill, and soon afterwards embarked for Scotland.

This inactivity on the part of their opponents, joined to the arrival of supplies from France, gave great confidence to the rebels, who now prepared to give consistency and colour to their proceedings, by the holding of a national convention. This accordingly met at Kilkenny, in October 1642. It consisted of the Catholic lords and clergy, besides deputies from the counties and towns in each province. By them were chosen 24 persons, who were styled the Supreme Council of the Confederate Catholics of Ireland. To this council the conduct of the war, and the choice and command of all officers, civil and military, were committed.

The convention professed themselves faithful to the king, but they denied the authority of his Irish government. The rights of the Catholic church were to be supported; and the law of England, so far as it did not contravene those rights, was, in conjunction with the statutes of Ireland, to form the guide of their public conduct. Generals were immediately appointed for the conduct of the war; but among these were not included Moore, or the other original leaders of the insurrection.

Opposed to this union of the Catholics, the loyal parties, as they were styled; would have been weak; even among the loyalists, if they had not been divided; but, in consequence of the contests between the king and his parliament, they were split into two parties. The lords justices, and those whom they influenced, adhered to the cause of the parliament; whereas Ormond, and the greatest part of the army, were royalists. These hoped that the insurgents might be induced to co-operate with them; and if they were, indeed, so disposed; but the lords justices had hitherto prevented their petition from reaching the king. Ormond at last interfered; their petition was laid before the king, and a commission was appointed to confer with the principal insurgents, and transmit their proposals. Charles was urged to this step, from the hope, that if he could gain them over; he might draw a large force from Ireland in support of his cause; while the parliament, on the other hand, were as anxious to prolong the disturbed state of the country. To effect this object any longer by intrigue, the lords justices now found would be impossible; they therefore agreed to permit Ormond (who, while the negotiation with the insurgents was pending, deemed it proper still to act against them) to attempt the reduction of Ross and Wexford, after having in vain endeavoured to place one of their own parties at the head of his army. Ormond immediately laid siege to Ross, but was repulsed in an assault; and the supplies of provisions which the justices had promised not arriving, he was compelled to raise it. He was now in a perilous situation, and, had the enemy kept possession of a defile in which they were posted, his ruin would have been certain and complete; but they left it, and Ormond, attacking them with impetuosity, defeated them, and effected his escape. His victory would have been more complete, if he had not been abandoned by the English cavalry under Lord Lisle.

After much delay and many difficulties, the nego-
Ireland.

tion with the insurgents was brought to a favourable
issue. On the 15th of September a treaty was signed,
by which the confederates stipulated for the payment
of £30,000 to the king, partly in money and partly
in provisions. Immediately on the conclusion of this
treaty, upwards of 2000 of Ormond's soldiers were sent
to England to assist the king; but the confederates,
though they had professed their attachment to him,
sent him no assistance.

At this period Ireland was in a very unsettled and
divided state; the confederates attended more to their
own plans and interests than to those of the king, by
whom Ormond had been appointed lord-lieutenant.
In the north, the partisans of the parliament were most
numerous; and Munroe, who commanded there, receiv-
ed a commission under the seal of the parliament, by
which he was constituted commander of all the forces
in Ulster, both Scotch and English; and ordered to
carry on the war against all those who refused to subscribe
the solemn league and covenant. Immediately on the
receipt of this commission, he surprised Belfast, and
deceived, though without success, to take Lisburne
also.

In the mean time, the Irish confederates resolved to
take advantage of the misfortunes of the king. Ac-
cordingly, during a negotiation at Oxford, they propo-
sed terms, which, if complied with, would in fact put
an end to the English power in Ireland; but
Charles, though now reduced to great distress, refused
to accede to them. The negotiation was protracted till
the year 1645, when two treaties were entered into;
one secret, under the management of the Earl of Gla-
morgan, and the other open, under the management
of the Earl of Ormond. By the former, with which
Ormond was not acquainted, the royal word was en-
gaged by Glamorgan for the re-establishment of the
Catholic religion and the papal authority; while, by the
latter, the civil and political demands of the confede-
rates were settled. The general assembly, on their
part, passed a resolution, that 10,000 men should be
raised for the service of the king. But these conditions
were nearly rendered void, by the arrival and inter-
ference of the Pope's Nuncio, who protested against
the treaty of Glamorgan, because it did not go far enough
in favour of the Catholics, and because it was to be
kept secret: and he prevailed on that nobleman to sign
additional articles, to the effect that Catholic bishops
should sit in parliament; that only a Catholic should be
appointed lord-lieutenant; and that the supreme
council should continue its authority till the whole trea-
try was complied with.

In the mean time, the English parliament supplied
the Protestant forces in Ulster with money; and one
of their partisans having prevailed on them to advance
into Connaught, they took possession of Sligo. To re-
take this place the Archbishop of Tuam and Sir James
Dillon marched by order of the confederates; but being
defeated by the parliamentarians, in the archbishop's
baggage, which was taken, was found a copy of Gla-
morgan's original treaty with the confederates, and also
of his commission and of his oath. These papers being
sent to the English parliament, were immediately pub-
lished, and injured the cause of the king very much in
the minds of all those who had hitherto supported him,
in the belief that he was not disposed to restore the
Catholic religion. The ministers of Charles, in order to
wipe off this impression, arrested Glamorgan, who con-
fessed that he had acted without particular instructions,
and solely on his own judgment, in order to benefit the
king. It is difficult to ascertain the truth respecting this
transaction; the probability is, that Glamorgan acted
rather on his idea of what the king would accede to,
and what would be advantageous to him, than on any
express orders or directions.

As however Glamorgan was arrested for his part in
the treaty, the confederates were alarmed and indig-
nant; but at length were persuaded to renew the ne-
gociation; and on the 28th of May 1646, it was brought
to an amicable termination. On the part of the king
he bound himself to grant toleration to the Catholics,
and the confederates on their part engaged to trans-
port 6000 well appointed infantry, and if they were
not sent at the time specified, the treaty was to be void.
But the sild thus at last obtained came too late. The
affairs of the king were irretrievably ruined. Find-
ing that it would be useless to send the forces into
England, it became a matter of deliberation in what
manner, and in what part they should be employed in
Ireland; but Ormond refused to act till his treaty
should be published, and that with Glamorgan cancelled.
This was accordingly done; but it soon appeared
that the peace which this treaty concluded was acceptable
to neither of the parties who were most interested in it,
and on whose good will it, depended mainly for its
efficacy. The Covenanters in the north, and the Par-
liamentarians in the south of Ireland were determined,
if possible, to root out popery; and the most numer-
ous party, as well as the most active and powerful
of the Catholics, were as determined to use all their ef-
forts to extirpate heresy. To these the Pope's Nuncio
attached himself; and Owen O'Neil was appointed by the
Pope's Nuncio to be the commander of what were called the Nuncio's
soldiers: these consisted of a desperate banditti; and
this circumstance, as well as the extravagant views of
the Nuncio, alarmed the more considerate of the con-
federates, and they actually commanded an armed op-
position against the troops of O'Neil, on account of the
irregularities which they committed in Leinster.

As soon as O'Neil had collected about 5000 infantry,
and 500 horse, he advanced towards Armagh, and was
followed by Munroe, at the head of the Scotch forces.
A battle took place between them, at a place called
Benburb, a short distance from this town, which ended
in the defeat of Munroe, with the loss of 3000 men, his
artillery, and most of his baggage. O'Neil's forces now
rapidly increased, and at the head of 10,000 men, he
was preparing to reduce Ulster, when he was recalled
by the Nuncio, in order to oppose the peace.

The Nuncio, supported by a victorious army, was
now more violent than ever, in his opposition to the
peace, as well as more haughty in his declarations of
the pope's authority. Ormond was now seriously
alarmed and perplexed; his treaty was abrogated by all
parties: the Nuncio and O'Neil openly opposed it; the
other forces of the confederates under Preston had dis-
band themselves for want of pay, and part of them
had gone over to the clergy: on the other hand, the
troops of the Parliament were still continuing their
hostile operations. Under these difficult circumstances,
Ormond put himself at the head of 2000 troops, for
the purpose of supporting the authority of the supreme
council, and enforcing the treaty; but his force was
inadequate, especially after the Nuncio had gained over
Preston, and Ormond was obliged to seek safety in the
capital.

The united troops of Preston and O'Neil lost no time Dublin be-
in advancing against Dublin, which was immediately sieged.
besieged. As Ormond could not expect to defend it
long, he was obliged to submit either to the English parliament, or to the Irish generals. He preferred the former alternative; his overtures were accepted; and 2900 men were ordered to march to the immediate relief of the city. In the mean time disputes had arisen between O'Neil and Preston, which probably would have produced a separation, if not mutual hostilities, had not the intelligence of the advance of the parliamentarian forces arrived. In consequence, however, of some difference between their leader and Ormond, they refused to act, and were sent back to Ulster. Ormond was now obliged reluctantly to give his sanction to the attempt which had been previously made to separate Preston from O'Neil; but his suspicions with regard to the former being soon confirmed, he saw himself again reduced to the necessity of submitting to the English parliament. Accordingly, on the 29th of June 1647, a treaty with the parliament was signed. The king's garrisons were to be delivered up to the commissioners of parliament, and the commissioners on their part promised security to such of the recusants as did not engage in rebellion; liberty for all to leave Ireland who chose to accompany Ormond; and the repayment of a large sum which he had expended in the service of the king.

Immediately on the conclusion of the treaty, Jones, the parliamentarian governor of Dublin, marched against Preston; at first he was unsuccessful, but being reinforced, a desperate battle took place at Dunganhill, in which the army of Preston was routed with dreadful slaughter. O'Neil was immediately called to the defence of Leinster by the Nuncio and his party, who rather rejoiced than grieved at the defeat, as it thus rendered O'Neil of more consequence.

In Munster the forces of the parliament were commanded by Lord Inchiquin, and the Catholic army by Lord Tanche. The latter was as anxious to avoid a general battle as the former was to draw it on; and for this purpose, as well as to obtain subsistence to his troops, he reduced the castle of Cahir, and thus opened to himself the fertile plains of Tipperary. He next took Cashel by storm. Tache was soon obliged to put himself in motion, and to hazard a battle. The two armies met at a place called Knockness, and the Catholics were defeated with great slaughter. The state of the confederates, at least of the more moderate part of them, seemed now desperate; their two principal armies under Preston and Tache had been defeated, and it might be apprehended, that as soon as spring arrived, the army of the parliament would follow up their success to the complete destruction of their cause. Thus situated, a new attempt was made to treat with the King, or rather with the Queen and Prince of Wales, who were at this time in France, while the Nuncio, by his emissaries obtained the sending at the same time a despatch to the pope. The Queen promised to send a person in a short time to Ireland; and the moderate confederates were privately assured that this should be Ormond.

This pleasing intelligence was soon followed by the defection of Inchiquin from the Parliament; but as the Nuncio still continued opposed to all moderate measures, the affairs of the confederates were more injured by him than they were benefited by any other circumstance. He even influenced O'Neil so far as to induce him to declare war against the supreme council, and to his army all who were inimical to the peace and to the English flocked. It became therefore necessary to proclaim O'Neil a traitor, which was accordingly done.

In 1648, Ormond arrived; his first object was, if possible, to unite the Protestant and Catholic royalists; and this object was rendered more attainable by two events; in the first place, the return of the Nuncio's commissioners from Rome without supplies or even promises of assistance; and secondly, the intelligence that the English army had demanded the death of the King. Peace, therefore, was concluded on nearly the same terms as in 1616; all the penal statutes against the Catholics were to be repealed, and they were to be allowed the free exercise of their religion; but the point relative to the establishment of the Catholic religion was left unsettled.

The intelligence of the execution of Charles, which arrived soon afterwards, proved that this treaty could be of no service to the royal cause in England, by enabling Ormond to send Irish forces thither; but in other respects this event, by the indignation which it excited, was beneficial to the royal cause in Ireland. Of this indignation, Ormond resolved to take advantage without loss of time. The governor of Dublin was, however, firmly attached to the parliament, and Sir Charles Coote, who occupied Derry, returned no answer to Ormond's offers. On the other hand, the British forces in Ulster declared for the royalists, and blockaded Coote. Ormond soon found, however, that he could not take advantage of the favourable change of circumstances, without a supply of money to support his troops; and this he could not obtain; the confederate Catholics could not raise it, and Prince Rupert, who had come to Ireland for the express purpose of aiding Ormond, not only refused to supply him with money, but even embarrassed his plans.

Jones, the governor of Dublin, a man of penetration, intrigue, and activity, was not, in the mean time idle; he even endeavoured, and not without success, to detach O'Neil, and carried his intrigues into the very heart of Preston's army. Ormond, though disappointed in many of his expectations, was convinced that if he was inactive, or discovered his disappointment, he would injure the royal cause; he therefore put his troops in motion, and being sensible of the effect which would be produced on all parties, by gaining possession of the capital, he took advantage of Jones having marched to some distance from it, and laid siege to it.

He had some expectation that on his approach, such of the inhabitants as were royalists, would discover them-
For this purpose a detachment was sent off, but it was led astray by the treachery of the guide; and Ormond found himself under the necessity of hazarding an engagement. Before, however, he had commenced the attack, his army was itself suddenly attacked, and thrown into utter confusion, by Jones. Eighteen hundred prisoners were taken, and 600 men were slain, Ormond himself retiring to Kilkenny with the remains of his army.

As some counterbalance to this misfortune he received overtures from O'Neil, which being accepted, and that leader having joined him with 6000 foot and 500 cavalry, Ormond resolved to make another attempt against the capital. Scarcely, however, had he formed this plan, when he learned that Cromwell had landed in Dublin, with 8000 infantry, 4000 cavalry, a formidable train of artillery, and every thing else necessary to carry on the war with vigour, promptitude, and effect. The first effort of Cromwell was the reduction of Drogheda; in it Ormond placed a chosen garrison of upwards of 2000 men, commanded by a Catholic, on whose bravery and skill he placed the utmost confidence. As it was the grand purpose of Cromwell to strike terror into his opponents by the boldness and rapidity of his operations, he issued orders to take the town by assault, and though the garrison resisted with the most determined bravery, and twice repulsed the assailants, yet they could not stand the third assault, at the head of which Cromwell placed himself. The town was taken by storm, and the garrison and Roman Catholic priests found in it, were put to the sword. Losing no time in reaping the advantages of the success and of the dismay which it had created, he took Trim and Dundalk without opposition; and while he himself marched towards the south, the whole of the north, except the castle of Carrickfergus, submitted to his authority.

Cromwell having reduced Wexford, notwithstanding Ormond had thrown a garrison into it, pursued that general, who had retired to Ross, and afterwards having crossed the Barrow, compelled him to retreat further to Kilkenny. Indeed Ormond, unless reinforced, was utterly incapable of standing against Cromwell; and the only source from which he could look for reinforcements was by an agreement with O'Neil. This general was himself dangerously ill; but having come to an accommodation with Ormond, he sent his army, consisting of a very large body of troops, to join him. Ormond immediately resolved to give battle to Cromwell, but the latter had proceeded to Waterford, which he was besieging. Into this place Ormond threw reinforcements, but a detachment from his army having failed in their attempt to reduce Carrick on the Suir, he did not deem it prudent to attack Cromwell.

Having received intelligence, however, from the inhabitants at Waterford, that they could no longer hold out, he resolved, at all hazards, to attempt their relief; and he succeeded in throwing in a second reinforcement, and in obliging Cromwell to raise the siege. Had he been supplied by the inhabitants with boats, and thus enabled to cross the river, he would have pursued Cromwell; but not only were these refused him, but his request that his soldiers should be permitted to lodge in huts under the walls was rejected; and it was even proposed to seize his person. This extraordinary display of ingratitude arose from the influence of some bigoted and ignorant priests in Waterford, aided and fostered by the Marquis of Antrim, who wished to supplant Ormond in the chief governorship.

Cromwell, on his retreat from Waterford, took up his winter quarters in Munster; the principal garrison in this province having declared in his favour, in consequence of the insults they received from the Catholics. Ormond, not supposing that his opponent would leave these quarters till the spring, had dispersed his troops in various places; but as soon as Cromwell learned this, he suddenly advanced, in the depth of winter, and laid siege to Kilkenny, which most probably he would not have reduced, had it not been for the treachery of the mayor and citizens. His next object was Cromwell. This place was garrisoned by 1200 troops under Hugh O'Neil; and such was their intrepidity; that in his first assault Cromwell lost 2000 men. This obliged him to commence a blockade; and O'Neil, after a siege of two months, being exhausted of his provisions and ammunition, and yet unwilling to surrender, contrived to withdraw his troops, with which he arrived safe at Waterford.

In consequence of the Scotch having embraced the cause of Charles II. Cromwell judged it expedient to return to England, having previously placed Ireton in the command of the army which was to act against Ormond and the Irish confederates. But there was now little to do; the greater part of Ireland was subdued: Cromwell had been very successful in the south; and, after his departure, Carlow, Waterford, and other places of importance, were surrendered. Limerick, too strong to be taken by assault, and even by a regular siege, till Ireton was reinforced, was blockaded.

In the north, Coote had reduced Carrickfergus. To the juncture of the forces of this general, and of Ireton, for the purpose of subduing the western counties, there was now no impediment, and for this purpose they both marched towards Athlone, while Ormond, with the few troops he could collect, directed his march to the Shannon, to prevent the enemy from passing that river.

The cause of the confederates, bad as it was rendered by the success of Cromwell, was made still worse by their own violence, opposition to Ormond, and want of plans and unanimity among themselves. Ormond and the royalists wished merely to support the king's cause; many of the confederates went rather farther than this; and the Catholic clergy made no scruple in avowing that they still indulged the idea of establishing their own religion, under the protection of a foreign prince. Even the inhabitants of Limerick, though sensible of the dangers with which they were threatened, refused to admit 1800 men, with which Ormond proposed to reinforce the garrison. An attempt was indeed made to arrange matters in such a manner that Ormond might act with effect in favour of the royal cause; but these attempts having been rendered of no avail by the intrigues of the violent Catholics, Ormond, unable to keep his army on the Shannon, destitute as it was of support or supplies from the inhabitants, and even apprehensive for his own safety, resolved to leave Ireland. But this resolution he changed when the Catholic clergy required him to repair to the King, declaring that now he would not quit the kingdom unless forced to it. This declaration produced formal articles against him, in which he was accused of being an
On the death of Cromwell, when the restoration of Charles II. seemed probable, the royalists in Ireland began to resume their intrigues, in which they were so successful, that in a short time they made themselves masters of the castle of Dublin, Athlone, Limerick, Drogheda, and in fact nearly the whole kingdom, and Charles was proclaimed in all the great towns.

While the royalists were thus advancing their own interest, and that of the king, the old Irish Catholics, as usual, were indulging in proceedings and schemes the most violent and outrageous; these were represent-
ed to his majesty as in fact rebellious; and the conse-
quence was, that Charles, on his arrival in London, issued a proclamation commanding a prosecution of all Irish rebels. The settlement of the lands was the next object of the king; and a declaration for this purpose was issued in May 1659. The great end in view was the compensation of all the innocent and meritorious Irish; but, in doing this, it was necessary to preserve the soldiers such lands as had been allotted to them. The first and second classes were the Protestants or Catholics, to whom no lands had been assigned in Connaught; next the innocent who had taken decrees for such lands; then those who had been dispossessed by the first two classes were to receive their reprisals, as it was called; and, lastly, those Irish were to be restored who claimed the benefit of the peace of 1648, or who had served abroad under the king. Such lands as might remain after these grants, were to be given as a recompense to those who had supplied, previously to 1649, arms, provisions, &c. Three new lords justices were appointed. Charles' next step related to the church; the four archbishops, and 12 bishops, were filled with some of the most eminent clergy, which was a prelude to the regular and full re-establishment of Episcopacy.

It was in vain, however, that the king expected, by these measures, to satisfy all parties, or to restore unanimity and satisfaction to a country which had been so long the prey of discord and discontent. The settlement of the lands was displeasing to almost all classes; and the interests of the old Irish Catholics, the other Catholics, the Protestant royalists, and the Puritans, were so much at variance, that the discontents arising from the settlement were much extended and deepened.

In vain a parliament was summoned, to sanction by their vote the proceedings of the king; in the Commons, the majority was returned by those who were adverse to the Catholics, as they possessed the greatest parts of the land, and the whole interest in the corporations. The Catholics had no members, and little influence in it; and it was even proposed that a law should be passed to exclude them. But the Commons, not being able to carry this law, they endeavoured to raise alarms of conspiracies; but here also they were disappointed. There was also a difference of opinion between the two houses regarding the settlement; the Commons wished to pass it into a law without any alterations, whereas the Lords wished to make such alterations as justice seemed to demand. As the king would of course decide those differences of opinion, the various parties sent agents to London. It was now that the Catholics felt the consequences of their former violent and disloyal conduct; proofs of all their proceedings were laid before the king, who, from these, was convinced that they had tendered the sovereignty of Ireland to the Pope; and, if he declared it, to any other
Catholic prince. Orders were immediately issued that no further petition should be received from the Catholics of Ireland.

Ormond, on the contrary, was rewarded by being appointed lord-lieutenant, by a present of £50,000 from the Irish parliament, and by his son being called to the House of Peers. Another source of discontent now arose: the administration of the act of settlement, though it was intrusted to English commissioners, unconnected with Irish interests, was said to be performed in a partial and unjust manner; and the discontent thus originating were carried so far as to produce several conspiracies, one of which had for its object the seizure of Dublin castle; they were all however frustrated.

In 1665, a bill of explanation of the act of settlement was brought into parliament; but it was not without a great deal of difficulty and management, that, even with this bill, Ormond could obtain the passing the act of settlement; and that only on the assurance that whatever was objectionable in it should be removed by the discretionary power which was vested in the governor and council.

Narrow and short-sighted views on political economy, acting in union with the opinion that Ireland, as a conquered country, ought in every respect to be sacrificed to England, gave rise to an act prohibiting the importation of Irish cattle into England. As some counterbalance to this unjust and impolitic measure, Ormond gave every encouragement to Irish manufactures, especially to the revival of that of linen, which had been established by Wentworth.

The conduct of Ormond, through the whole period of his command, and after he became lord-lieutenant, had been marked by wisdom, moderation, and justice; but though thus distinguished, and though his attachment to the royal cause was undoubted, he could not escape from the intrigues and machinations of that junto in England, known by the name of the cabal. He was obnoxious to them on those very accounts which made him the favourite of every real friend of his country; their schemes against him were deeply laid, and at last they succeeded in bringing him into disgrace with the king. The charges against him were examined before the privy council; but they were so evidently unfounded, that Charles restored him to the government of Ireland, in which he continued, in spite of the intrigues which were still carried on against him, the difficulty of keeping the Catholics quiet, and other circumstances, which would have puzzled, and probably been the ruin of a man possessed of less firmness, circumspection, and honesty, than Ormond, till James II. ascended the throne.

Two lords-justices were appointed to succeed Ormond; and it soon became evident that their situation would be surrounded by difficulty and danger. The Catholics, existing in the known character and principles of James, were extremely violent in their language and measures, while the Protestants found themselves exposed to their rancour, in consequence of an order from the king that the militia, who were all of this persuasion, should be disarmed, under the pretence that they might favour the rebellion of Monmouth. The apprehensions of the Protestants were but too well founded; they were haunted every where, and upon every occasion, by informers; the most absurd and impolitic accusations were brought against them, and their lives were thus rendered miserable from continued apprehension.

The designs of James to subvert the Protestant reli-
The town had been first assaulted on the 17th of April. On the 30th of July, three ships were seen in Loch Foyle, part of those which had before appeared there. On these vessels the eyes both of the besiegers and besieged were anxiously fixed. The attempt to approach the town was extremely difficult and hazardous; and the besiegers now did every thing in their power to increase the difficulty and danger. Where the lake narrowed, its shores were lined with battereys, and a boom formed as strong as it could be made, was stretched across this narrow part. This boom consequently must be broken, before the vessels could possibly approach. One of them came near it. All eyes were fixed on the event. Sailing with considerable velocity, she broke the boom. The besieged were almost intoxicated with joy, when the next moment their joy was changed to despair, on observing the vessel on shore, in consequence of the rebound given her in breaking the boom. The next moment, the recoil of her guns, which were fired on the besiegers as they attempted to take possession of her, again set her afloat. The garrison were now relieved from famine; and as on famine alone the besieged had trusted for success, they immediately retired, having lost 8000 men. Of the 7500 of which the garrison consisted, 4500 survived; but a large proportion of these were incapable of service.

As soon as the Protestants of Enniskillen learnt the issue of the siege, they went in pursuit of the enemy, and not only harassed them, but by their rapid excursions, struck terror even to the capital. At length three different armies were sent against them. Two of these they defeated, and the third, under the Duke of Berwick, they obliged to retreat.

In the mean time, James in Dublin had assembled a parliament, composed almost entirely of Catholics. The acts of this parliament were by no means calculated to repress the violence of James' adherents, from which, indeed his cause suffered as much as from the opposition of the adherents of King William. Among the first acts of this parliament, were the repeal of the act of settlement, and the passing an act of attainder. The last was equally distinguished by its impolicy, injustice, and cruelty. But, indeed, the proceedings of James were attended by such blind folly as it could have fallen into, whose intellect was not completely subdued by bigotry, and who had not given himself entirely up to the guidance of men of the most desperate character. It is not possible that he ever could have reflected on the possibility of such measures restoring him to the throne; or how, if restored, he could hope to reign, except these measures were continued, to keep down the hatred which they excited.

The Protestants, exposed to every species of outrage, had long looked for effectual succours from England. At length they arrived under Schomberg and Solmes. From Bangor, in the county of Down, where Schomberg landed, he advanced to Dundalk, taking possession of Belfast, Antrim, Carrickfergus, &c. on his route. His encampment at Dundalk was very injudiciously chosen in a low and damp spot, by which sickness attacked his troops. Against him, thus encamped, the army of James marched, commanded by him in person. The situation of Schomberg, though unhealthy, was strong; so that James, after making a shew of immediate and general attack, retired to Ardee. The people of England having indulged in great hopes from the operations of Schomberg's army, were loud in their expressions of disappointment and indignation, when they learnt that his plan seemed rather defensive than
William resolved, in order to pacify the people, to go himself into Ireland; and he accordingly landed at Carrickfergus on the 14th of June, 1690.

Having put himself at the head of his forces, the army of James retired before him to the southern side of the Boyne, near Drogheda, where it halted; James, who had joined it from Dublin, declaring his resolution to try the fate of a battle. The hostile armies were nearly equal, that of James consisting of 33,000 men, and that of William of 35,000 men. The army of the former was composed of French and Irish; that of William of Dutch, Danes, and other foreigners, among whom were some Huguenots, and English and Irish; the last were principally Enniskillen Protestants. The position of James' army was strong; but William, after having reconnoitred it, resolved to cross the Boyne and attack him. For this purpose, he formed his army into three divisions, with orders to pass the river in three different places. The right wing crossed early in the morning of the 1st of July without opposition, and, by their manœuvres, soon put to flight those of the enemy with whom they had to contend. The passage of the centre division was not effected so easily; and, after it was effected, the Huguenots were thrown into disorder. To retrieve which, Schomberg put himself at their head, and, being taken prisoner, he was accidentally killed by the fire of his own men at the same time fell George Walker, the heroic defender of Lounderry. The object of the King himself, who headed the third division, was, after crossing the river, to take the enemy in flank; but the English cavalry under his immediate command, could not withstand the impetuous attack of their opponents, and were forced to give way. In this dilemma, William rode up to the Enniskilleners, and asking them "What would you do for him?" they immediately advanced, charged the enemy in the most brave manner, and thus afforded time for the cavalry to rally. The infantry of James now gave way; and James himself, alarmed at his danger, put himself at the head of a regiment of cavalry, and gained the pass of Duke's; three miles to the south of the field of battle. The rest of his forces having also passed through this defile, formed again, and effected their retreat in good order. The loss of the vanquished is said to have been 1,500, and that of the victors 500.

James fled with such rapidity, that he reached Dublin that night. He stopped there a very short time; and after having advised his partizans to submit to William, he continued his route, and embarked at Waterford for France. His army also retreated by Dublin; but they directed their march towards Athlone and Limerick, highly disconcerted with James' conduct during the battle, and with his desertion of them after its unfortunate issue.

The King did not attempt to pursue the defeated army; but having received the submission of the garrison of Drogheda, he advanced slowly to the south, and encamped about two miles from Dublin. A proclamation was immediately issued, promising pardons and protection to the lower orders of men who had remained at home, or should return thither, and give up their arms; but expressly excluding from pardon the leaders of the rebellion. Commissioners were also appointed to seize all forfeitures rising from the rebellion.

As the enemy's forces had retreated to Athlone and Limerick, it became necessary to take measures for following and reducing them. Accordingly, after William had permitted his army to rest a short time, he detached ten regiments of infantry, and five of horse, towards Athlone, while he himself marched southward with a larger force. Athlone was first attacked; but William's troops being repulsed, their commander judged it prudent to give up the enterprise, and to march to join the King. The great object of the monarch was the reduction of Limerick. He began his approach to this city, which was very strong, on the 9th of August. The garrison was commanded by Boileau, a Frenchman, who took every measure that skill and experience could suggest for the defence of the place. One of his first enterprises was to intercept an escort, and succeeding in this, he gave fresh spirit to his troops, and an earnest to William of the difficulties he might expect to encounter. The King, however, was naturally of a temper not easily damped or dispirited. He proceeded in his plans, and, on the 18th of August, was enabled to open his batteries. On the 27th, having effected a breach, an assault was ordered; but after this attempt had been carried on for the space of three hours, William was obliged to retreat, with a loss of 500 killed and 1000 wounded; and soon afterwards he ordered the siege to be raised, and his army to retreat to Clonmel. Thence he himself proceeded to Waterford, and embarked for England. On his departure, the command of the forces was left to Count Solmes and Ginkel, and the care of the civil government to two lords justices.

The Earl of Marlborough, afterwards so famous, had, before William raised the siege of Limerick, sailed from Portsmouth with 5000 men; and, landing near Cork, he reduced this place and Kinsale. This event, so prejudicial to the cause of James, was almost immediately followed by the departure of Boileau and his French soldiers from Limerick, between whom and the Irish there had long been much jealousy.

The Irish were not, however, dispirited by these events. On the contrary, they prepared for an attack on the garrison at Mullingar, and, for this purpose, had collected forage for 5000 cavalry for five days at Athlone. Ginkel, on learning this, resolved to anticipate the attack, and, marching at the head of 3000 men from Mullingar, he attacked a considerable body of the Irish, who were encamped at Hollymore. The attack succeeded; the enemy fled; but, rallying at a place called Grenoge, they again gave battle, and were again defeated, and thrown into complete disorder. By this defeat, their plan of offensive operations against the English garrisons was frustrated.

The partizans of James would probably have given way to despair, had it not their hopes been kept up by the promise of supplies from France; but only officers came, and among them Saint Ruth, who was empowered by James to take the command of all his troops in Ireland. This general, after having learnt the number of the forces which he was to command, and of those by which he would be opposed, deemed it prudent to act solely on the defensive; and he therefore strengthened his posts on the west side of the Shannon, while with his main army he took his station behind Athlone.

Against Saint Ruth thus situated, Ginkel resolved to commence offensive operations. On the 18th of June, he came in sight of the town; a breach was soon made in the wall of what is called the English town, and that part was taken by storm; but it seemed impossible to reach the Irish town, the bridge being bro-
IRELAND.

Saint Ruth, immediately on the reduction of Athlone, retired with his army, which consisted of 25,000 men, to the heights of Kilcommeden. Here he took up a strong position, and awaited the approach of Ginckle, who was not slow in following him, notwithstanding his army consisted of only 18,000 men. This inferiority, however, was amply compensated by the spirit by which his soldiers were actuated. Indeed a most bloody contest was about to take place. The first effort of Ginckle was to force a pass on the right of the enemy; and this having been effected, his whole left wing advanced through it, and attacked the right of the Irish. The contest was severely contested; and the Irish, even after they were obliged to give way, retired only to flank their assailants in their turn. Saint Ruth, as soon as he was informed of the attack on his right, drew great part of his cavalry from his left to support it. Advantage was immediately taken of this, and orders given to force the pass of Aghrim Castle on the left of the enemy by the cavalry, while the infantry made a movement to support this attack. The latter charging with im petuousity, the enemy designedly gave way, and the assailants, pursuing too far, were overpowered by a charge on the front and flank at the same time. The cavalry, however, had succeeded in their object, which induced Saint Ruth to make them the principal object of his attack. But, while he was giving orders to that effect, he was slain by a cannon ball. The disputes between the French and Irish now produced the most fatal results; for Saarfield, the Irish general, being totally unacquainted with Saint Ruth's plans, was unable to follow them up, and, before he could decide in what manner to act, the English were victorious. Their loss was only 700 killed and 1000 wounded, whereas the Irish lost 7000, besides 450 prisoners, and all their cannon, ammunition, &c.

Allowing his troops a few days repose, Ginckle marched against Galway, which soon surrendered, on condition that its garrison should be permitted to march to Limeric. The terms in other respects were liberal as well as politic; for, as soon as they were known, considerable numbers deserted the cause of James. Still, however, his partizans were numerous, and such as remained firm, were animated by a most determined spirit of resistance.

No place of consequence now remained to James except Limeric, and thither Ginckle directed his march. Recollecting, however, the ill success of his master before this place, he resolved to proceed with the utmost caution. He took measures to prevent the garrison receiving supplies by sea, and to secure his own communication with Kerry, in case he should be obliged to take up his winter quarters there. As the garrison was equal in numbers to his own army, it would have been madness to have attempted to have taken the town by assault. Instead, therefore, of wasting his time in making breaches in the walls, he resolved to cut off their provisions, by cutting them off from the county of Clare, whence they were drawn. This enterprise was successfully performed, to the surprise and consternation of the Irish, who, when they saw the batteries dismantled, thought that the siege was about to be raised.

The next object of the general was to gain possession of Thomond Bridge and King's Island, which lie to the north of what is called the English Town. The Shannon was crossed, the works that protected the bridge were taken possession of, and, after a desperate resistance, the English made a lodgment within ten yards of it. Ginckle was surprised at his own success; but a general engagement which the enemy ought to have hazarded on this occasion, was prevented by the disension between the Irish and the French. This dissention, together with the success of the English, produced an offer to capitulate; and Ginckle here, as at Athlone, gave the most liberal terms. In a few days after Limeric was thus reduced, a French fleet appeared in the Shannon, with such supplies of troops, &c. as must have rendered it impossible, if they had got into the city, to have taken it.

The articles of Limeric, as they are called, that is, Articles of the terms on which this city, and all the other posts in possession of the adherents of James, were surrendered, were in substance as follows: 'That the Catholics should enjoy such privileges in the exercise of their religion, as were consistent with law, or such as they had enjoyed in the reign of Charles II.: That their Majesties, as soon as their affairs would permit, should summon a parliament, and endeavour to procure from it such further security as might preserve them from being troubled on account of their religion: That all the Irish in the kingdom in the service of James, should be pardoned, and exempted from all actions for debt, on account of plunder committed by them in the course of the war; That they should be reinstated in their property, and in their rights and titles, as soon as they took the oath of allegiance, enjoined by an act of the English parliament in the first year of King William's reign: That every lord and gentleman, who was included in this capitulation, should be allowed to carry arms for defence or amusement; that the garrisons should march away with all the honours of war: And that those who might choose to leave Ireland, should be permitted to carry off their effects to any country except Britain, ships being provided for that purpose by the British government. Fourteen thousand Irish availed themselves of this article, and left their native country.'

As William was now completely master of Ireland, it was hoped and expected that he would immediately summon an Irish parliament, but this he did not do till 1692, when he wanted money. In the mean time the English parliament legislated for Ireland; the most important of their acts was one to substitute other oaths, instead of the oath of supremacy, which, in fact, excluded Catholics from both houses of parliament. In 1692, when the Irish parliament met, it became evident that the commons were disposed to stand up for the rights of their country much more firmly than William wished or expected; they even went so far, as to contend that Poyning's law did not extend to money bills, and rejected one that was sent over to them from
History of Ireland.

England, expressly because it had not originated with them. This parliament was therefore dissolved, in the hope that the next would be less sturdy in the maintenance of their privileges.

In 1692, a new parliament was assembled, which, among other things, explained and confirmed the act of settlement, and confirmed the articles of Limerick, but not without such modifications and alterations as were by no means consonant to their spirit, and therefore were not justifiable; this parliament also passed some penal statutes against the Catholics. The great majority of its members were by no means disposed to question the authority of the English parliament; but some of the members of the commons stood resolutely up, not merely for the independence of the Irish upon the English parliament, but even for the independence of the kingdom of Ireland upon the kingdom of England. These doctrines were maintained with great spirit, acuteness, and reason, in a work published by Mr. Molynux, one of the members from the university of Dublin, which so incensed the English House of Commons, that it was burnt by the common hangman.

So jealous and sensitively alive did the English government appear to be to the rivalship of Ireland in manufactures, that whenever, by being rendered tranquil, she was in a state to carry them on, it immediately interfered to injure such kinds of manufacture, as could in the smallest degree compete with those of England. Against the woollen manufacture their decrees were most violent and frequent; and the linen manufacture, which the English government professed to encourage, was suffered to languish, till formidable rivals to it arose both in England and Scotland. The climate of Ireland, and the richness of her pastures, especially near the Shannon, pointed out the rearing and fattening of cattle, as her most proper and profitable species of agriculture; and yet embargoes were laid on the exportation of Irish provisions. In short, Ireland was treated not only as a conquered country, but as a country, so formed by nature, that if left to itself, it must unavoidably get the start of England; and these two considerations, in the opinion of the English government, appeared to justify its conduct towards her.

William, in his conduct towards Ireland, does not deserve so much censure as the English parliament, which forced these measures upon him; they were jealous of almost every thing he did; sometimes because they thought the liberties of the people might be injured, but more frequently, from regard to their own privileges. In order to reward some of his favourites, the king had made several grants of the forfeited estates in Ireland; this displeased the English parliament, which passed a bill to resume these grants, on the ground that they ought to have disposed of them, and that the money they produced ought to have gone to the public; and the king most reluctantly was obliged to give his assent to this bill, and thus annul his own measure.

The reign of Queen Anne, so far as it regards Ireland, was distinguished principally by the severe penal statutes which were passed in the Irish parliament against the Catholics. It never seems to have occurred, that excess of severity only tended to increase the bigotry and ignorance against which it was directed, and that mild measures, aided by endeavours to enlighten the Catholics and adopt them in the spirit of charity, without a constant reference to the state of Ireland as a conquered country, would much more effectually have promoted the object which the British government, and, under their influence, the Irish parliament, professed to have in view. But, besides the irritation which was thus produced among the Irish Catholics, the Irish nation in general were constantly reminded, in the most galling and unnecessary manner, of the dependence of their parliament upon that of England; and the violence of party—always great in Ireland, was augmented by the English government, to serve the paltry purposes of political intrigue.

In the year 1719, a circumstance occurred which pointed out the pertinacity with which the British parliament were resolved to crush every symptom of an independent spirit in the parliament of Ireland. It was necessary to take the judges' opinion, whether, by the laws of the land, an appeal could be made from the Court of Exchequer in Ireland to the King in Parliament in Great Britain. The answer was in the negative. This point afterwards came before the British House of Peers, who were highly indignant at the determination of the question, and at the conduct of the Irish Peers, in resolving to support the independence of their country; they even brought in a bill, which passed into a law, entitled an Act for the Better Securing the Dependency of Ireland on the Crown of Great Britain, in which the British Parliament was declared to have full power and authority to make laws and statutes of sufficient force and validity to bind the people of the Kingdom of Ireland.

In 1724, Swift distinguished himself by the Drapier's letters, the object of which was to point out the consequences that would result from a patent granted to a man of the name of Wood, for supplying Ireland with a copper coinage. Such was the ferment occasioned by these letters, that the patent was revoked next year. It is now pretty well ascertained that Swift was not the patriot he was then considered, and that Wood's coinage (though the granting him a monopoly was improper and unjust) would by no means have been the source of profit to himself, or so prejudicial to the people, as was represented in the Drapier's letters. But Ireland, at this period, was admirably adapted to be the scene of every kind of political imposture and intrigue. She was miserably governed; her interests were never consulted, but always sacrificed either to the interests of England, or, what was worse, and more provoking, to the interests of such individuals as the British ministry wished to oblige. The viceregal power came over once in two years. The effective power was with the lords justices, and their time and thoughts were occupied in forwarding the plans of the British cabinet, and promoting their own private interests.

The privileges of the Catholics, already greatly curtailed, were still further encroached upon, by an act passed in 1727, by which they were totally deprived of the elective franchise. Such, however, was their attachment to their native soil, that, though a scarcity, reaching almost to a famine, drove thousands of Protestants to America, scarcely any Catholics emigrated.

The grand political parties at this time consisted of British and those who, on all occasions, endeavoured to promote the English interests, even at the expense of the interests of their own country, and those who called themselves patriots, and who professed to look only to the advantage of Ireland, and to regard that advantage as an interest also for the British parliament. In the Duke of Dorset's first administration, which began in 1731, there was a grand struggle between these two parties in the parliament: Those in the British interest were desirous of granting the sup-
Dispute about vested rights.

A.D. 1749.

In 1749, the power of the Irish parliament was again brought under discussion, in consequence of the intended application of the surplus of the hereditary revenue of the crown towards the payment of the national debt. The question was, whether the right of disposing of this surplus was vested in the king or the Irish House of Commons; or, in other words, whether his majesty's previous consent was necessary. At this time the English party gained their point; but when the question was renewed in 1753, the patriots were victorious.

A.D. 1755.

At length, in 1755, the British government seemed disposed to accede to the wishes of the Irish nation, and to think that the real interests of Ireland ought, at least in some degree, to be consulted. Stone was removed from the privy council by the king's command; Boyle was created Earl of Shannon; and several others of the patriots were placed in situations of emolument and influence. But it soon became evident that the patriots, as they styled themselves, had carried on the struggle with the crown, rather to support and extend their own influence, than from any regard to the wishes, or real benefit of the people. In fact, it had been too much the struggle of the aristocratic party against the crown; and while they were kept out of office, they took the side of the people, in order to strengthen themselves, which they were too much disposed to desert when they had brought the crown to their own terms.

In 1756, the real sentiments of the aristocracy were displayed: A bill was brought into parliament, to vacate the seats of such members of the House of Commons as should accept any pension or place of profit from the crown. This bill was thrown out by a majority of 26. As the passing of this bill would have told against the patriotic party when they came into power, it was ominous to them; but they gave their support to those measures which tended to support the privileges of parliament, or to benefit the country, without trenching on their own interests.

It is not to be supposed, that a country such as Ireland was at that time—with the great majority of its population ignorant, bigotted, and with a government constantly inattentive to, if not absolutely sacrificing its interests; and with the spirit of enterprise and industry, wherever it started up in spite of these obstacles, crushed by the mean jealousy of Britain—could be rich: it was in fact poor; and the national poverty was greatly increased by the failure of some of the principal banks, and an extreme scarcity, and consequent high price of grain. In the midst of the discontent which arose from these causes, a report was spread that Ireland was to be united to England—to be deprived of its parliament—and to pay the same taxes as England. The mob of Dublin took the alarm, and broke out into the most riotous proceedings, which, however, were of very short continuance.

In 1759, Britain and Ireland were alarmed with the A.D. 1739. preparations for invasion making in the French ports; but no landing took place, except that of Thurot with 600 men at Carrickfergus, and he re-embarked in the course of a few days. The conduct of the Irish troops, as well as of the peasantry, on this occasion, proved that they were much more loyal and worthy of confidence than they were allowed to be by those who calumniated them, for they were eager to rush to the defence of their country; and such as were engaged behaved with surprising zeal and intrepidity.

We now come to the time of the first appearance of those associations of the peasantry, and others of a higher class, for purposes of outrage, or of effecting political objects, by which the history of Ireland is henceforth so much distinguished. In 1762 the Whiteboys first created alarm. They took this name, which succeeded that of Levellers, from the circumstance of their putting on their ordinary dress by a short or white frock. They consisted of labourers in the woolen manufacture, who had been driven out of employment by its decline; and of labourers in husbandry, who had been reduced to the same state, in consequence of the general conversion of arable into pasture land. To add to their distress, at this time a spirit of enterprise and improvement had recently promoted the enclosure of commons, on which these people had previously enjoyed the right of commonage. The outrages of the Whiteboys were dreadful; and the alarm was greater than even they warranted, in consequence of a suspicion that they were instigated by, and connected with, the Catholics. The next year an insurrection arose in Ulster. In this only Protestants were concerned. The cause of this was the hardships under which, it was alleged, the poorer classes laboured with regard to keeping the roads in repair. The insurgents called themselves
IRELAND.

Hearts of Oak, from wearing oaken branches in their hats. They soon, however, carried their views beyond their original object; and, on their proceeding to interfere violently with regard to this, and the rent of land, they were put down by an armed force.

The first circumstance, after the accession of George III., connected with the history of Ireland, that deserves our notice and record, was the passing of the octennial bill in 1768. The Parliament of Ireland, unlike that of Britain, continued in existence as long as the monarch lived, being dissolved only by his death taking place. In 1761, an attempt was made by Lucas and others of the patriotic party, to limit the duration of the Irish parliament, and to place it on the same footing in this respect as the British parliament; this however did not succeed, and it is even doubtful whether the British government intended that the measure should be carried in 1768; for the British privy council returned the heads of a bill transmitted to them for limiting the duration of the Irish parliament to seven years, with an alteration which extended the duration to eight years; probably expecting that, by this interference, the Irish parliament would be induced to reject the bill altogether; but the Irish parliament, with great temper and good sense, passed the bill as returned to them.

At this period Lord Townshend was lord-lieutenant:
His favourite and principal object was to destroy the power of the Irish aristocracy, and to take out of their hands the influence and distribution of places and pensions, which had been hitherto allowed them, in consequence of the supposed necessity of securing their favour and votes. This was a difficult point; but the victory, -capital in it, through justice, even that of the most justifiable means. From this time, the lord lieutenant, or in other words, the British government, was regarded and treated as the only source of honours or emoluments. During the administration of this nobleman, who was very popular among the Irish, not merely on account of his public measures, but also on account of his dispositions and manners, open and convivial, and thus highly congenial to those of the people over whom he was placed, some disturbances broke out in Ulster, in consequence of a system introduced there of letting land on fines. As the great majority of the small farmers and peasantry were totally unable to pay these fines, and were consequently deprived of their farms, they became desperate, and committed such violent outrages on those who had taken their lands, that government was obliged to have recourse to military force. The insurrection was thus quelled; but the distressed inhabitants, deprived of the means of subsistence, were driven to America in great numbers.

We now approach one of the most interesting and important areas in the history of Ireland. From the conduct almost uniformly pursued by the British government towards this country, as we have detailed it, it must appear evident, that Ireland could never expect to obtain freely from Britain, those privileges and that treatment, which, had the government of Britain been wise, she would have been anxious to grant, not merely from a feeling of justice, but from a view to her own real interests. Neither this feeling, however, nor this enlightened and liberal view of her own interest, which her conduct of Britain to Ireland had been with scarcely a single exception, marked by mean and narrow jealousy; and, what was worse, by a determination, which ought not to have found a place in the mind of Britons, who prided themselves on their love of freedom, to treat Ireland in every respect as a conquered country.

To Ireland there appeared no chance of escaping from the degradation and thralldom in which she was thus involved, when the American war broke out. This immediately produced a remarkable change in the language and conduct of the British government as they related to Ireland; proposals were made in the British House of Commons in favour of Irish commerce; and some of the penal statutes against the Catholics were annulled. They were now enabled to acquire full property in land, and a son could no longer force a settlement from his father by conforming to Protestantism, provided the Catholics subscribed an oath of allegiance and a declaration, which were prescribed. Still, however, Irish commerce and trade languished, and the patriots of Ireland aimed at much greater privileges with respect to it, and to their political state in general, than had yet been granted.

The means by which their views might be forwarded were at hand. The American war had drawn from Ireland nearly all her regular forces, and her coasts, thus unprotected, were exposed to invasion. In consequence of the town of Belfast not receiving a garrison adequate to their protection, the inhabitants, in 1779, entered into armed associations to defend themselves against the enemy. This gave rise to the system of volunteers, which soon spread over the whole country. The Irish now began to feel their strength, and even the House of Commons unanimously passed a resolution, on the first day of their session this year, that, in their address to the king, it should be represented to his majesty, that "it was not by temporary expedients, but by a free trade alone, that Ireland could now be saved from impending ruin;" and in order to give effect to this address, they voted their supplies only for six months. A motion was also made, that the granting of new taxes would at that time be inexpedient, which was carried by a large majority. Thanks were voted, unanimously, in the House of Commons, and, with only the dissentient voice of the Lord Chancellor, in the House of Lords, to the volunteers, for their exertions in defence of their country.

Lord North, who was at this time prime minister, now found himself obliged to give way; but hoping that the Irish would be content with the removal of commercial restrictions, he carried a bill through the British parliament, which in some measure respected that object. But the Irish looked to greater objects; and, unfortunately for his own views, Lord North, in order to induce the British manufacturers and merchants to agree to his commercial concessions, had represented them as a boon resumable at pleasure. The Irish thus learned, that what had been granted, had been granted, either through fear, or as a matter of favour, and not as their right, and they became sensible that they could not be secure, unless they had an independent legislature of their own. Resolutions to this effect were published by the different volunteer corps, who, in order that they might act with more effect, formed a union among themselves, and they were not only animated by the same spirit, but, in all their resolutions and proceedings, directed to the same object.

This spirit animated all ranks and classes; it was no longer an association confined to one part of the kingdom, composed of ignorant and poor men, without talent or influence, and aiming at some local and temporary object. At the head of the Dublin volunteers
IRELAND.

was the Duke of Leinster; and, on the 9th of June 1780, with him in the chair, they resolved, "That the king, lords, and commons, of Ireland, only are competent to make laws binding the subjects of this realm; and that they would not obey or give operation to any laws, save only those enacted by the king, lords, and commons, of Ireland, whose rights and privileges, jointly and separately, they were determined to support with their lives and fortunes."

The House of Commons, which had hitherto gone along with the sense of the nation at large, seems now to have been replaced under ministerial influence, at least to have been of opinion that the nation were proceeding too rapidly and rashly; for a motion made by Mr. Grattan, that no power on earth, save the king, lords, and commons, of Ireland, had a right to make laws for Ireland, was withdrawn; and the Irish parliament, acting in the spirit which caused this motion to be withdrawn, passed into laws two bills which had been altered by the British cabinet. Hence the parliament became very unpopular.

In the year 1781, the force of the volunteers had been augmented to 50,000 men, regularly divided into regiments, and in high discipline; and in order to give full effect to the object they had in view, the Ulster volunteers resolved to send delegates to Dungannon, to deliberate on the state of public affairs. This measure, however, was by no means approved of by some of the most judicious and sincere friends of the volunteers. The meeting took place, and some very strong resolutions were passed, in which most of the grievances under which Ireland had so long laboured, were dwelt upon in a bold and indignant spirit; it was further resolved, "that four delegates should be nominated for each county in Ulster, to act as representatives of the volunteers in that province, and that of these, eleven should form a quorum; and that this committee should appoint nine of their members for a committee in Dublin, to communicate with other volunteer associations. The parliament, however, were still adverse to the measures which the volunteers had in view, and refused to interfere in favour, either of the commercial or the political amelioration of Ireland. With respect to the Catholics, however, they were more liberal, and scarcely a session passed in which some of their disabilities were not removed.

The volunteers, having formed their committees of correspondence, and a national committee, had thus given to their system a single animating spirit, by which their powers was wonderfully increased; and if the British government still refused to comply with their requests, a crisis was necessarily take place, which would probably end in warfare. At this period, full of alarm to the best friends of their country, that administration which had lost Britain her American colonies, resigned; and they were succeeded, in March 1782, by a Whig administration, at the head of which was the Marquis of Rockingham. The Duke of Portland was immediately appointed Lord Lieutenant. Mr. Grattan moved an address to the king, in the House of Commons, which was unanimously carried in both houses, in which it was declared, that "the crown of Ireland was an imperial crown, inseparably annexed to the crown of Great Britain; but that the kingdom of Ireland was a distinct kingdom, with a parliament of her own, the legislature thereof; that in this right they conceived the very essence of their liberty to exist; that in behalf of all the people in Ireland, they claimed this as their birth right, and could not relinquish it but with their lives; that they had a high veneration for the British character; and that their determination was in sharing the freedom of England, to share also her fate, and to stand or fall with the British nation."

The Lord Lieutenant assured parliament that the British legislature had concurred in a resolution to remove the causes of their discontent; and that his majesty was graciously disposed to give his royal assent to acts calculated to fulfill their wishes. As an earnest of the sincerity of this declaration, a law was passed, by which all interference of the British privy council to alter Irish bills was abolished, and the parliament of Ireland thus placed on the same footing as that of Britain; and acts were passed for the limitation of the law against mutiny to two years; for the right of habeas corpus, and for the independence of the judges; and the act by which the Irish House of Peers had been deprived of their supreme judicial power in their own country, was repealed. These concessions, however, were not deemed sufficient by some patriots, particularly by Mr. Flood, who brought in a bill, declaring the sole and exclusive right of the Irish parliament to make laws in all cases whatsoever, both internal and external, for the kingdom of Ireland: only six members voted for this motion. Mr. Grattan opposed it, and the volunteers of Leinster, Ulster, and Connaught, were likewise inimical to it.

The volunteers having accomplished the objects which they originally had in view, did not disdain themselves, but directed their views and exertions to reform in parliament. In order to act with vigour and effect, they followed their former plan of a national convention, which they appointed to be held in Dublin on the 10th of November, 1783. On the 29th of the same month, a motion was made in the House of Commons by Mr. Flood, founded on the resolutions of this convention, which, after a long and warm debate, was rejected by a very large majority. This termination, instead of rousing the volunteers to perseverance, as it would have done, when they had their original object in view, seems to have disconcerted and alarmed them; for the convention adjourn'd to an indefinite period, in vain... after having passed a resolution to carry on individually, their efforts for parliamentary reform; and having agreed to address the king, expressing their loyalty, and beseeching him not to ascribe their efforts to reform the constitution to its pure and pristine form, to any love of innovation, or want of attachment to his government or power. Soon after this the volunteer system declined, ministers hastening its decline by raising fencible regiments, into which they drew the officers of the volunteers by pecuniary inducements.

The cause of parliamentary reform, though no longer supported by the volunteers in their associate character, was not deserted by the people, or by its advocates in parliament; and their hopes were raised by the circumstance, that Mr. Pitt, who had been its most strenuous supporter, was now prime minister. It was soon found, however, that Mr. Pitt was no longer of the same opinion; and Mr. Flood’s motion for leave to bring in a bill to reform the Irish House of Commons, was negatived, though not till after a long debate. The advocates for this measure, out of doors, were not cast down; the citizens of Dublin, legally convened by the sheriffs, voted a series of resolutions in favour of this measure, and also appointed a committee to prepare an address to the people at large, National and a petition to the king. The people were invited to a congress, to form a national congress, composed of five persons...
from every county and large town; and the meeting of
this congress actually took place in Dublin, on the 25th
of October, 1784, notwithstanding the endeavours of
government to prevent it, which were carried, at least,
as far as the law warranted.
At the first meeting nothing of importance was done;
but, at the second meeting, at which there were assem-
bled above 200 members from 27 counties and most of
the large towns, it was resolved to petition parliament,
but to leave the specific form of redressing the
grievance complained of to be determined by the wisdom
of the legislature.
Though Mr. Pitt was inimical to parliamentary re-
form, both in Britain and Ireland, yet he was disposed
to free the commerce of the latter country from some of
the restraints under which it laboured, and to protect
it from foreign competition. But his attempts to es-
ablish a more advantageous system of commerce between
Britain and Ireland, were in a great measure defeated
by the jealousy of the British manufacturers and mer-
chants. This obliged him to new model the proposi-
tions which he had originally sent to Ireland, and which
were adopted by the legislature there with the most per-
fected and cordial approbation, to such a degree, that
when they were again introduced into the Irish House
of Commons, they passed in the Irish parliament, with
a majority of 19 in a house consisting of 235 members.
This trifling majority induced the Irish government to
withdraw them altogether. The system of tithes has
always been a source of ill will, even where those who
paid them were of the established religion; but it seem-
ed very hard and unjust to the Catholics, that they
should pay towards the support of a clergy whose ser-
tices they did not need, nor wish for. Besides, the
tithes pressed hard on the poor renters of a piece of
ground, perhaps scarcely large enough to support a
man and his family, even if he had received the whole
produce. From this feeling with regard to the oppres-
sion of tithes, arose, in 1786, a species of insurrection
in the south of Ireland, carried on by persons who styled
themselves Right-boys. They administered oaths,
binding the people not to pay more as the tithe of an
acre, than a sum they fixed—to permit no preachers—
and not to allow the clergyman to take his tithes in
kind. Not being sufficiently opposed in this outrage,
they proceeded farther; to fix the rents of land—to
raise the wages of labour—and to oppose the collection
of the tax called hearth-money. This called forth the
attention of the legislature, and in 1787 an act was
passed, to prevent tumultuous assemblies and illegal
combinations.
From this time till the illness of his majesty in 1789,
nothing important in the affairs of Ireland occurred.
On the occasion alluded to, ministers found themselves
deserted by so many of their friends, that they were
left in a minority in both houses; and it was resolved
to request his Royal Highness the Prince of Wales to
take upon him the government of Ireland, during his
majesty's indisposition, under the title of Prince Re-
gent, with all the legal prerogatives belonging to the
crown thereof. The awkward situation into which the
two countries would thus have been thrown, by the Re-
gent's power being restricted in Britain, and unrestric-
ted in Ireland, was prevented by the fortunate recovery
of his majesty; and this circumstance restored to the
Irish ministry their majorities in both houses.
The American revolution, as we have seen, produced
a wonderful effect on the affairs of Ireland; the French
revolution, which commenced about the time of the
King's illness, was destined to affect the affairs of Ire-
land in a still greater degree, but unfortunately not in
so favourable a manner. It was natural that those in
Ireland, who had been so long and so ardently endea-
vouring to gain for their own country what they deemed
its rights, and essential to its prosperity, should re-
joice at the French revolution when it began, and that
they should feel by it inspired to renew their attempts
to obtain their favourite objects of parliamentary reform
and Catholic emancipation. The hopes in which they
might hope to attain these objects seemed pointed out
to them by the volunteers—by union and associations
they had prevailed, and thus also they might be equally
successful. Accordingly, in June 1791, there ap-
peared at Belfast the plan of an association, under the
name of United Irishmen; and in November this asso-
ciation was actually instituted at Dublin; their decla-
red object was, "the forwarding a brotherhood of af-
feciton, a communion of rights, and a union of power,
among Irishmen of every religious persuasion, and
thereby obtaining a complete reform in the legislature,
found on the principles of civil, political and religious
liberty." Such were their avowed objects; but there
is reason to believe, that, even at the first formation
of this association, the leading members looked rather
than a reform of the legislature into a revolution of
soil necessary to obtain their professed objects by means
inconsistent with public tranquillity, and with their
duty as subjects. That they had such a necessity in
contemplation, is evident from the formation in Dublin
of national guards, distinguished by a green uniform,
and by buttons with a harp under a cap of liberty in-
stead of a crown. The 9th of December 1792 was ap-
pointed for the general muster of these guards, and all
the volunteer companies were invited to attend; but
the muster never took place, in consequence of the
strong measures of precaution adopted by government.
Thus prevented from assembling, the leading men
among the United Irishmen put forth a paper, signed by
Archibald Hamilton Rowan as their secretary, in which
they expressed their expectation that the volunteers would
resume their arms for the maintenance of tranquillity
against foreign and domestic enemies, and the Protestants
generally to choose deputies to a national convention,
with which, when formed, the Catholics might act. The
Catholics, as might be supposed, were not indisposed
to take advantage of this state of the country. Besides
the grievances which were common to them and the Protest-
ants, they had various grievances of their own, arising
from their religion; and from the declaration of the
United Irishmen, they were led to hope that the Pro-
testants, so far from opposing their claims, would now
co-operate with them in their endeavours to obtain
them. Accordingly they also had their convention,
which assembled on the 3d of December, 1792, in Dub-
lin. After voting a petition to the king, and appointing
a permanent committee for the management of Catho-
lic affairs during the recess, they adjourned. That
the real nature of the claims which they put forth might be
understood, and the objections generally urged against
their claims being complied with might be removed,
they abjured the dangerous tenets which they were com-
monly supposed to entertain—that excommunicated
princes might be murdered or deposed by their sub-
jects; that the murder of heretics is lawful; that no faith
is to be kept with them; that they could be absolved
from their oaths of allegiance; that the pope had any
jurisdiction within the realm; or that any human power
could forgive sins, without sincere repentance. They
The United Irishmen and the Catholics, both looking forward to a change in the laws, were naturally well disposed to each other; but from other quarters the claims of the Catholics were most violently opposed. The government seemed to think that the safest conduct for them to pursue was to avoid both extremes; they were not disposed to grant all the Catholic wishes, nor to withhold every thing. In conformity with this determination, in 1793, the legislature admitted the Catholics to the practice of the law—to intermarry with Protestants—and to an unrestrained education. The legislature, during this session of parliament, also passed a law to prevent the election, or other appointment, of conventions, or other unlawful assemblies, under pretence of preparing or presenting public petitions, or other addresses, to his majesty or parliament. This act was directly aimed at a proposed meeting of a national convention of the United Irish at Athlone, which was prevented. A report of a Secret Committee of the House of Lords threw much light on the views and proceedings of the United Irishmen, as well as on those of a description of insurgents called Defenders. The latter were Catholics in Armagh, Louth, Meath, and the adjacent counties, who, having first associated to defend themselves against the ill treatment inflicted on them by gangs of Presbyterians, called Peep-of-day Boys, became afterwards the assailants.

From this description of the state of Ireland at this period, it will be evident that there was much discontent and dissatisfaction among the great mass of the people; and this discontent was much augmented by the measures of raising a militia, on the plan of that of England, which caused some serious disturbances, besides a good deal of misery, among those who could not serve themselves, and were not able to pay for substitutes.

We have already mentioned, that Archibald Hamilton Rowan was secretary to the United Irishmen at the time their manifesto was published; he was on that account arrested, and in 1794 brought to trial. It was suspected at the time of his trial, that the views of the United Irishmen went farther than they avowed, and that the utter subversion of the constitution, and the separation of Ireland from England, was in their contemplation, and the object of their meetings and schemes. This was afterwards proved on the trial of an English clergyman of the name of Jackson, for a reasonable correspondence with the agents of the French government; for Rowan, who had been condemned to a fine, and imprisonment for two years, contrived to escape out of prison, and fled out of the country, conscious that, on the trial of Jackson, evidence of his real designs would be brought to light. Jackson was condemned, but he took poison, and expired before he was removed from court. Two others, who were leading men among the violent democratic party, Napper Tandy and Theobald Wolfe Tone, the principal framers of the United Irishmen, also fled from their country. Indeed, there was now too much reason to believe, that the United Irishmen not only aimed at a separation from Britain, but aimed at this object by means of the co-operation of France—a method at once most dangerous to that liberty which they professed themselves so anxious to secure, and utterly at variance with real patriotism or enlightened views.

There seemed two modes by which, at this time, Ireland could be restored to a state of comparative satisfaction and quiet, either by giving way to the more open views of the United Irishmen, by conceding parliamentary reform, or by separating the Catholics from them, by granting Catholic emancipation. The people of Ireland believed that the British ministry had chosen the latter method, when Earl Fitzwilliam arrived among them as viceroy; for he had been intimately connected with the Whig party, though he had differed from them respecting the French revolution, and he had succeeded to the estates, and it was believed inhaled the virtues and principles of the Marquis of Rockingham. According to his own statement, the truth of which rests on his character, and on the circumstance that it was not proved to be false by ministers, no restrictions had been imposed upon him when he accepted the government of Ireland, but he was left completely at liberty to take such measures to restore tranquillity and loyalty to the country, as he deemed necessary and expedient. His first measure showed that he was in earnest; for he began by displacing those people in power, who had opposed the system he meant to pursue. Soon afterwards, petitions were prescribed from the Catholics, praying for the repeal of all their remaining disqualifications, and leave was given, almost unani mously, to bring in a bill agreeably to these petitions. In the mean time, those who had been removed from office had not been idle, especially one of the Beresford family, who had been removed from a situation of considerable emolument. A rumour was spread that Lord Fitzwilliam would be immediately recalled. The Catholics took the alarm, and petitioned the King against his removal. To this no answer was given; and on the 25th of March Lord Fitzwilliam left Ireland. The bill introduced into the Commons for the relief of the Catholics was still before them; but, on the second reading, the same House of Commons who had before almost unanimously supported the bill, threw it out. The Catholics, however, were permitted to send their sons to study in the university of Dublin; and a college, endowed by government, was established for them at Maynooth.

The conduct of the British government was by no means calculated to pacify the Catholics. Disturbances prevailed through the country. A mob in Dublin, attacked and wounded the Lord Chancellor, Fitzgibbon—a man who was peculiarly obnoxious—and defender ism increased. The Catholics, however, were not nearly so dangerous as those who aimed at political changes. The United Irishmen now began to direct their views and plans with less scruple, though with more secrecy, to the most reasonable designs. Secret associations were formed, of which no person was admitted a member, till he had solemnly sworn that neither hopes, fears, rewards, or punishments, should ever induce him, directly or indirectly, to inform on, or give evidence against, any member or members of that or similar societies, for any act or expression of theirs done or made collectively or individually, in or out of the society, in pursuance of the spirit of the obligation by which they were distinguished and bound.

In public as well as in private transactions, extreme violence on one side is too apt to beget extreme violence on the other. The government deemed it absolutely necessary to deprive the subject of the protection of those wholesome and just laws, by which, in times of internal tranquillity and universal loyalty, his life and property as well as his liberty were protected. They deemed...
ed it also necessary to pass laws of great rigour and severity, the execution of which must be left, in many cases, entirely to the local magistrates, or to the commanders of the troops stationed where the disturbances took place. These magistrates and commanders, too often even by the authority of government with a discretionary or arbitrary power, were apt, even where they were men who were conscientiously desirous to act right, and only to exercise severity where it was absolutely necessary for the preservation of the public peace, to pass beyond the limits of their power. This was too frequently the case. Men guilty, or suspected of being dangerous to the public peace, were seized by the magistrates, and sent to serve in the navy. In order to protect the magistrates from the consequences of this stretch of power, a bill of indemnity was passed; and likewise what was called the insurrection act, by which the chief governor in council was authorized to proclaim, on the requisition of seven of its magistrates assembled at the session of the peace, any county or district thereof in a state of disturbance, and thereby to invest the magistrates with a power, under the authority of the law, to send suspected persons into the navy. They were also authorized to search houses for arms, and, after previous notice, to treat as culprits all as should be absent from their homes, without satisfactory excuse, after certain hours in the evening. In October 1796, the Habeas Corpus act was again suspended.

In order still further to protect the country from the designs of the disaffected and against a French invasion with which it was threatened, the Government encouraged the formation of an armed yeomanry. In many respects, this species of force was much preferable to the troops of this line, on which hitherto the peace and defence of Ireland had mainly depended; for those troops, principally from Britain, had certainly served to irritate and inflame the Irish by their disorderly conduct; besides, the formation of yeomanry was judicious and beneficial, as it might have a tendency to break down the associations of Orangemen in the north of Ireland, who, under pretence of defending themselves from the Catholics, were guilty of the most frightful outrages and violations of the laws.

It was not to be supposed that the French government was ignorant of the state of Ireland, or indisposed to take advantage of it in their war with Great Britain. Indeed it was matter of surprise that they had not attempted to land troops in a country so disturbed, and in which there was avowedly so numerous and active a part of the inhabitants desirous to throw off the British yoke, and for that purpose, to accept any foreign assistance that might present itself. An agreement was in fact made between the leading men in the Irish Union, and the French Directory, for the landing of a French force in Ireland, on condition that the invading army should act as auxiliaries, receiving their pay and instruction from the Union. As soon as this arrangement was settled, preparations for the invasion of Ireland were made at Brest. The Irish Union, in order to be ready to second the efforts of their new allies, were uncommonly active and zealous in their preparations and plans; but, in the midst of these, they were thrown into a state of uncertainty, and induced to suspend their operations, in consequence of receiving, first, the intelligence that the invasion would take place immediately, that is, in the beginning of the winter of 1796; and almost immediately afterwards, a letter, which they had no reason not to regard as authentic, declaring that the invasion would be deferred till the spring of 1797.

The invading fleet, however, anchored in Bantry Bay, on the 24th of December 1796; but as the general, and a great part of his troops were on board ships which had not arrived, the admiral, after waiting for him a few days, returned to Brest, having previously ascertained, however, that the country was well defended, and that even the peasantry, towards whom the French had been taught to look for immediate and hearty co-operation, were apparently adverse to them.

A proclamation was issued on the 17th of May, 1797, declaring the civil power inadequate to quell the insurrection; and this proclamation was followed by orders for the military officers to act without waiting for any authority from the civil power. The military, who had previously been highly irritated by the resistance of the insurgents, and who, it is too probable, had entered Ireland, with the belief that it might be treated in all respects as a conquered country, now gave way, in too many instances, to the most oppressive outrages. Under the pretence that arms were concealed, houses were sometimes burnt or plundered; and the military torture of the picket was employed to force a discovery. But it is painful to dwell on such outrages; suffice it to say, that they were such as might be expected from soldiers acting not only without the control of the civil power, but, as they believed, in furtherance of the views of government, against a people whom they regarded as proper objects of their tyranny and cruelty. The United Irish, perceiving that their only chance of success was by assuming the appearance of being reduced to obedience, and conducting their operations in a more secret manner, discontinued their meetings; and the state of the country generally improved so much, that in August 1797, the administration of justice was again committed to the civil power.

But the United Irish were only laying their schemes deeper, and were inactive and tranquil only, that they might burst out with more violence and effect. Hitherto they had been chiefly confined to the northern provinces; but now the associations began to extend to the western and southern parts of Ireland, and the whole organization to assume a military form. According to their new plan, the lowest societies consisted of 12 persons, who lived near one another, and among whom there was frequent and confidential intercourse. Five of these societies elected each a secretary, and these secretaries formed a baronial committee, which had the superintendence of the first society. Ten of these lower baronial committees elected each a delegate, and the ten delegates composed an upper baronial committee, which directed the business of the ten lower committees. In like manner was the organization of county, district, and provincial committees effected. The supreme command was lodged in an executive directory, which was composed of five persons, unknown to all except the secretaries of the four provincial committees. From this directory the orders were conveyed in the most secret but efficient and prompt manner; and they were instantly and fully obeyed. Such was the civil organization of the Irish Union. The military was organized like it, and, in fact, was grafted upon it. The secretary of each of the lowest societies was its non-commissioned officer;

Kildare, East Meath, and King's County, their numbers were com-
paratively few; but they were using their utmost en-

endeavours to extend the Union all over Ireland.

As the attempt to reduce Ireland to order and tran-
quility by means of force had now been carried on for
a considerable time, without producing the effect ex-
pected and intended, it was hoped that the British
ministry would have adopted different measures, more
consonant to the spirit of the constitution, as well as
more satisfactory and pleasing to the friends of humani-
ty. Under this idea, Lord Moira and Mr. Fox moved
in parliament, that a humble address should be pre-
sented to his Majesty, praying him to interpose his pa-
ternal interference for the allaying of the alarming dis-
contents then subsisting in Ireland; but these motions
were negatived, as well as one which his lordship af-

dered made in the Irish House of Lords, where he of-
fered to produce proof of the most absurd as well as
disgusting tyranny ever exercised in any country. In-

deed, it was only through the debates in parliament that the real state of Ireland at this period could be learnt;
for the newspapers, which were in favour of the insur-
gents, as well as those of government, grossly mirepre-

sentedit. The former were most licentious and mischie-
vous in their representations, and also in their endea-
vours to spread the flame of sedition and rebellion; and,
in more than one instance, called down the vengeance
of government. As soon as the members of the Irish
Union found that they could not propagate their views
by means of newspapers, they had recourse to hand-bills,
which were privately printed and circulated by their
agents. In these, abstinence from spirituous liquors
was recommended, in order that the revenue might be
impaired; and this recommendation, which it might
have been thought no motive would have induced the lower
classes of the Irish to follow, was obeyed so gen-
erally and faithfully, that their habit of drunkenness
was to be decidedly more sober than usual. The members
were also cautioned against purchasing the quit-rents
of the crown, as the bargains would not be valid in case
of a revolution. A caution was also given against the
acceptance of bank notes. All these circumstances evi-
dently proved that the Irish Union were still in hopes of
accomplishing their object by a revolution; but, as
they could not hope for this by their own unaided ef-

orts, they again had recourse to France. Assistance
was readily promised them; and preparations for the
invasion of Ireland were made at Brest and in the Texel;
but the expedition from the latter place was rendered
abortive, by the defeat of the Dutch fleet at the battle
of Camperdown. Still the Irish Union looked towards
assistance from the Brest expedition; but the French

government appearing to have forgotten their promise,
Arthur O'Connor, who was a member of the Irish di-
rectory, was commissioned to proceed to France; but,
on his passage through England for that purpose, in
February 1798, he was arrested, along with an Irish
priest of the name of Coigly, and Binns, a member of
the corresponding society of London. They were tried;
O'Connor and Binns were acquitted, but detained on

another charge of treason; Coigly was condemned and
executed.

The Irish Union, thus disappointed in their hopes of
assistance from France, resolved to trust solely to their
own power. By this time, the number of men sworn
into the conspiracy amounted nearly to half a million,
and plans were formed for the simultaneous rising of
this body. Their object, however, was discovered by
a man of the name of Reynolds, who was a delegate for
the province of Leinster; and from his information,
the members who formed the committee of this pro-

vince were arrested. Emmet, Macenevin, and Bond,
members of the directory, were also arrested. Govern-
ment, at the same time, by the seizure of papers, were
made thoroughly acquainted with all the plans of the
Union, and thus were enabled to frustrate them. The
Union, thus deprived of their directory, proceeded to
elect new members, among whom were two brothers of
the name of Sheares; but neither these nor the other
members were equal in talents to the former members;
and yet greater talents were now requisite, not merely
on account of the discoveries made by government, but
also because the lower members of the Union, wearied
with waiting, and anxious not to much to accomplish
the political objects of the Union, as to gratify their own
private revenge, could not be managed except by men
of the greatest talents and influence.

On the 30th of March, 1798, government issued a
proclamation, which proved that they meant to adopt
the most vigorous measures which were in their power,
for the immediate suppression of the disaffection and
disorders in Ireland. In this it was stated, that "a
traitorous conspiracy, existing within the kingdom, had
been considerably extended, and had manifested itself
in acts of open rebellion; and that in consequence of
the most direct and positive orders had been issued
to the officers commanding his majesty's forces, to em-
ploy them with the utmost vigour and decision, for the
immediate suppression of this conspiracy, by the
disarming of the rebels, and all disaffected persons,
by the most summary and effectual measures." At the same
time General Abercrombie, who then commanded the
forces in Ireland, was directed by the lord lieutenant
to proceed with his army into the disturbed counties, vest-
ed with full powers to act as he should think proper.
His first object was to restore the discipline of the army,
which was in such a state, that it could not be safely
trusted with the execution of the orders he meant to
issue. Afterwards, on the 3d of April, he published a
manifesto, calling upon the inhabitants of Kildare, where
his head-quarters were fixed, to surrender their arms
within 10 days, and, in case of non-compliance, threat-
ening that large bodies of troops should live among them
at free quarters, promising rewards to those who would
give information of concealed arms or ammunition, and
denouncing other severities, in case the inhabitants
did not return to a state of tranquillity.

At the expiration of the ten days, the troops were
quartered on those who were known or suspected to be
disaffected; and their behaviour was such as in most in-
stances might be expected from men of their habits and
feelings, hitherto little accustomed to strict discipline.
The insurgents did not seem intimidated by these
proceedings against them; and as they were ignorant
that government were acquainted with their plans, they
still persevered in the determination to rise in a body
on a fixed day. Before that day arrived, however, go-

vernment caused Lord Edward Fitzgerald, who had
contrived the plan of attack, and who was distinguish-

Arrest of A. O'Connor.
A D. 1798
ed for his boldness, talents, and influence, to be arrested. He made a desperate resistance, and died soon afterwards of a wound which he received before he was taken. The two brothers Sheares, and other conspirators, were arrested the same month; and, on the 21st of May, the plan of insurrection was announced by Lord Castlereagh, secretary to the Lord Lieutenant, to the Lord Mayor of Dublin. The night of the 23d was the time fixed for it. An attack on the troops stationed near Dublin, and on the artillery, was to have been first executed. The castle was, about the same time, to have been surprised; after which, the parties engaged in these enterprises were to have united. The stoppage of all the mail coaches on the great roads, was to have been the signal for the rising of the people in the various parts of the country. The scheme was certainly well arranged, and had it not been discovered, might have been attended with the most disastrous consequences.

Rebellion began.

Even though thus discovered, the insurrection broke out in a manner that caused great alarm, and, for some time, exposed parts of Ireland to the horrors of a civil war. On the 24th of May, the insurgents, though they were nearly without leaders, and with scarcely any arms except pikes, commenced their operations by an attack on Naas, Carlow, and other places, from which they were repulsed with loss. They had previously destroyed the mail-coaches in their road to Dublin, to give notice to their confederates that they were about to commence their operations, and to retard the communication of them to government. As soon as the first acts of rebellion took place, General Lake, who had succeeded General Abercorn to the command of the forces, issued a proclamation, in which he expressed his determination to use, in the most summary and vigorous manner, the powers with which he had been entrusted to suppress the rebellion; and commanded all persons of every rank, except officers and magistrates, to remain in their houses from nine o'clock at night till five in the morning. Proclamations were also issued by the Lord Mayor of Dublin and the Lord Lieutenant. In the first, all persons in Dublin were ordered to give in a list of their arms, or to surrender them if they had not a licence to possess them; and every house-keeper to fix on the outside of his door a list of the names of all persons resident in his house. In the second proclamation it was stated, that orders had been sent to all his majesty's general officers in Ireland, to punish, according to martial law, all persons assisting in the rebellion.

The progress of the rebels towards the south-west was checked by their repulse at Carlow; but the city of Dublin was still partially blockaded by them. To complete the plan for its relief, Sir James Duff made a rapid march with 600 men from Limerick, and arriving at Kildare, opened the communication between the capital and the country.

On the 26th of May, the insurrection broke out in the county of Wexford, where it was not apprehended that the insurgents were in great force. They were headed by a priest of the name of Murphy, a ferocious and ignorant fanatic. On the 27th, two bodies of them made their appearance at Orlaith and Kiltomhas. At the latter place they were defeated by 400 or 500 yeomen; but at the former place, where Murphy himself commanded, they were victorious. Murphy immediately proceeded to Enniscorthy, of which, by the assistance of the Catholic inhabitants, he gained possession. The inhabitants of the city of Wexford were now in great alarm, as they could plainly distinguish the flames of the burning houses at Enniscorthy. As they were little prepared for defence, they resolved to negotiate with the insurgents, or, rather, to endeavour to persuade them to return peaceably to their homes. For this purpose, two gentlemen, who had been arrested on private information, were sent to them; but they kept one of these to be their leader, and sent the other back to Wexford. Against this place they now determined to proceed. Its small garrison took a position outside, but afterwards returned into the town, which was almost immediately evacuated, and taken possession of by Wexford the rebels. Their force was about 16,000 men; and by the capture of Wexford, the southern parts of the country, as well as the eastern and western, were at their mercy. They now divided into two bodies; one of which directed its march to Gorey, in the northern part of the county, in the hopes of thus forcing a passage to the capital, and the other to New Ross, by reducing which they would be enabled to enter the counties of Kilkenny and Waterford. The inhabitants of Gorey were apprised of their danger, but they trusted it would be averted by the arrival of troops under General Loftus and Colonel Walpole, which immediately marched by different routes to attack the insurgents, who were posted on a hill seven miles from Gorey, under the command of a priest of the name of Roche. This man seems to have been possessed of great military talents, for he immediately resolved to quit his position with his whole force, upwards of 10,000 men, and attacked Walpole while separated from Loftus' troops. He came up with him at Clough, and, attacking him quite unprepared, the British were defeated, with the loss of Clough; their artillery, Loftus, in the mean time, following the insurgents to Gorey, ignorant of the defeat of Walpole's corps, found them posted so strongly that he durst not attack them, but retreated into the county of Carlow.

The body of the rebels who had marched towards Ross were not so fortunate: They had chosen for their leader a person of the name of Harvey, whom they had liberated from Wexford jail. He formed a plan of attacking three separate parts of the town of Ross at the same time: The attack was accordingly made in a furious but irregular manner. At first the rebels gained some advantages, but they were soon thrown into confusion; and General Johnson, who commanded a strong party of the regular army in the town, took advantage of this circumstance, and, after a desperate resistance from some divisions of the rebels, while others were totally without discipline or management, he succeeded in completely defeating them, and in saving the place. Enraged at this defeat, the rebels massacred in cold blood more than 100 of their Protestant prisoners at Wexford.

The insurgents who had defeated Walpole's corps remained inactive for some time afterwards. At length, on the 9th of June, they advanced to the north to join another body of insurgents, and, when united, to attack Arklow. The garrison in this place, not conceiving themselves strong enough to defend it against the rebels, left it; but afterwards returned, in consequence of their not attempting to seize it. The rebels, however, changed their plans, and advanced against it; and on the very day of attack there arrived the Durham fencible regiment. The force now consisted of 1600 men, and, being arranged in line, with the artillery in front, they were enabled to cover three sides of the place, a river protecting the other side. The force of the insurgents amounted to more than 50,000, but
IRELAND.

only about 4000 or 5000 of these had guns. They advanced with great impetuosity to the cannons' mouths, but they were in every assault driven back with immense slaughter. The battle lasted four hours; and though, during the whole of that time, the Durham fencibles bore the brunt of it, yet they stood firm and undaunted. The pikemen of the insurgents had not, however, yet come into action, and General Neltham, apprehensive that the fencibles, wearied out with repeated attacks, would not be able to withstand these formidable assailants, sent directions to Colonel Skerrett, who commanded the fencibles, to retreat. This, however, he refused to do; and though it was now dark, and the insurgents might have profited by this circumstance, they discontinued the attack, and retreated.

The insurgents, of whom we have been hitherto speaking, consisted almost exclusively of Catholics. They hoped to be assisted in their plans by the Protestants of the north of Ireland; but in this they were disappointed. There were, indeed, insurrections in Antrim and Down; but the Protestants who engaged in them, after a few skirmishes with the royal troops, gave up the enterprise, chiefly in consequence of being assured that the rest of the Protestants in the north, though in general well disposed, would not cooperate with them. Having learned that the insurgents in Wexford was totally of a religious character, and that the Catholics engaged in it had repeatedly behaved with great cruelty to the Protestants.

The insurgents in Wexford were thus left to themselves, and measures were taken by government to crush them effectually and speedily. On the 20th of June, their whole force was assembled on Vinegar-hill, near Enniscorthy. General Lake immediately formed his plan, which was, to surround this post; and for this purpose, all the divisions of the royal army were put in motion.

In the mean time, the insurgents were guilty of the most atrocious acts of cruelty, not merely against those who had opposed their plans, but even against those who were known to be favourable to them, in case they were Protestants. These were dragged to Vinegar-hill, where, without trial, they were either shot or transfixed with pikes, or, in some cases, put to death in a still more barbarous manner. At Killan, the Protestants of both sexes were collected, with an intention of burning them alive in their parish church, when fortunately their design was prevented by the arrival of a body of yeomen.

General Lake had collected nearly 13,000 troops, with a train of artillery proportionate to that number, for the attack on Vinegar-hill. This attack took place on the 21st of June. The town of Enniscorthy was the first object of attack, and the insurgents were driven from their post. They fled through a space of ground which was to have been occupied by the troops of General Neltham. These had not come up, whether from missing the road, or some other accidental cause, or, as was supposed, because General Lake wished to leave the insurgents some outlet, is not ascertained. Wexford was taken by the royal troops the same day as Enniscorthy: Previously, however, a battle had taken place at Horetown, between the troops of General Moore and the insurgents under Roche. The combat was long doubtful, but at length terminated in the defeat of the rebels. General Moore immediately encamped near Wexford, in order to secure the Protestants in that town from massacre. Before his arrival, however, the rebels in it had committed great outrages.

These were principally directed and encouraged by a man of the name of Dixon. While the rebel force continued in Wexford, this man had not been able to carry his designs into execution; but soon after they marched out against General Moore, Dixon, at the head of a mob, which he had previously inflamed with whisky, murdered the Protestants in a manner to which, for wanton cruelty, not even the atrocities of the French revolution can produce a parallel. In the mean time, the battle at Vinegar-hill, though strenuously contended by the insurgents, ended in their complete defeat. They were completely broken, and fled; and their loss in the battle and pursuit was so considerable, that the whole party was completely disheartened.

Before General Moore arrived at this town, many of the inhabitants, being freed from the presence of the insurgents, who had joined their companions on Vinegar-hill, were desirous of submitting, and giving up the place. Lord Kingsborough, colonel of the North Cork militia, was at this time a prisoner in it; and he agreed to receive the surrender, pledging his honour for the safety of all, except those who had been concerned in the murders. On this pledge, which was made known to the British general, the insurgents were told that they had fled into the vinegar-hill, evacuated it, separating into two bodies, in the full confidence of the ratification of the terms; but General Lake ordered all the chiefs of the rebels to be seized and put to death.

The movements and proceedings of the insurgents, after the battle of Vinegar-hill, were desultory, without union or plan. One body of them marched to Arklow, and, finding no royal troops there, massacred many of the inhabitants. Another body, under Murphy, who had originally raised the insurrection in Wexford, directed their march towards the county of Carlow, with the design of stirring up the inhabitants there and in Kilkenny; but in this they were disappointed, partly by the measures of the royal forces, and partly by the indisposition of the inhabitants. They now determined to return to Wexford, and on the 25th of June arrived at Kilkenny. Here they again changed their route, and moved towards the Wicklow mountains, but were soon found that they had no other chance of safety but by dispersing into small bodies, being no longer capable of withstanding the forces that were sent against them. After various movements and skirmishes, therefore, they finally dispersed.

Government, in the mean time, had been proceeding Trials and in the trials of those leaders of the union whom they had apprehended. Among these were, the two brothers Sheares; McDursh, the secretary to the provincial committee of Leinster; and Byron, delegate from Wicklow.

Soon after these events, Lord Camden, who had been viceroy during the rebellion, was recalled, and Earl Cornwallis was appointed his successor. This appointment gave great and general satisfaction: The character of few noblemen, for political honour and humanity, was higher than that of Lord Cornwallis, and his appointment seemed a pledge on the part of government, that they meant to pursue a different system in Ireland. He carried with him a general pardon for all who would submit, with very few exceptions; but his arrival could not immediately put a stop to the system which had been hitherto pursued. On the 3d of July, the pardon which Lord Cornwallis brought with him was published in the Dublin Gazette. His majesty's generals were thereby authorised to give protection to such insur-
It is probable that the disturbances in Ireland would have been quelled much sooner than they actually were, had not the French invaded that country. The policy of the French with respect to Ireland is not easily understood. It seems as if they either should not have invaded it at all, or their invasions should have been better timed, and in much greater force. There is little doubt that, at more than one period, Ireland might have been wrested from Britain, if the French had landed with 15,000 or 20,000 men, and a large supply of arms. The Irish insurgents fought well; they wanted principally officers and arms; so that, if the French had supplied these, the fate of the country would probably have been decided. But to return from this digression. The Irish insurgents had been long anxiously expecting assistance from France; at last, when it was too late, a force of about 900 regular troops, commanded by General Humbert, landed at Killala, on the 22d of August, and, being joined by some of the Catholic inhabitants, immediately marched to Castlebar. As soon as Lord Cornwallis learned their arrival, a force was collected, and marched against them. General Hutchinson arrived at Castlebar on the 25th, and was immediately joined by General Lake, the chief commander on the west. The British troops were drawn up in an advantageous position between Castlebar and the French, who were advancing towards it. At seven o'clock in the morning of the 27th, Humbert arrived with about 800 of his own troops, and 1000 Irish peasants. His only artillery consisted of two small guns. The army opposed to him amounted to nearly 3000. Suddenly was the engagement begun, when the royal army were seised, with a panic and flight, leaving their artillery, which consisted of six pieces of cannon, and their ammunition, behind them. Their officers in vain attempted to rally them: They fled, without stopping, 38 miles, to Tuam, which they reached that night; and, at one o'clock of the 28th, some of them reached even Athlone, having marched 80 miles in 27 hours. Here they were stopped by the arrival of the vicerey.

From Castlebar, the French, after gaining this most unexpected victory, proceeded to the eastward, into the heart of the country, with what design it is impossible to conjecture, unless from the expectation of being reinforced by the peasants on their march. General Lake and his column followed to watch their movements, while Lord Cornwallis, with the chief army, moved towards Carrick, on the Shannon. At length, on September the 8th, General Lake having come up with their rear, at a place called Ballinamuck, a short action took place, which fortunately terminated in the surrender of the French, and the capture or dispersion of the rebels. The troops of Humbert amounted to 748 privates and 96 officers.

The French certainly had been disappointed in not receiving assistance from the Irish; but it is probable that, on the intelligence of their landing, and especially of their success at Castlebar, insurrections would have taken place in many of the adjoining counties, had not the march of Lord Cornwallis intimidated those who might be so disposed. Even as it was, there was an insurrection near Granard, the object of which seems to have been to take possession of Cavan, where there were large stores of arms and ammunition. Previous to this enterprise, however, it was necessary for them to take Granard; and in this they were disappointed by the arrival of some yeomanry from Cavan, by whom they were defeated. They afterwards sustained another defeat, which put an end to the insurrection. The Catholic peasantry of the county of Mayo, who had first risen to assist the French, still continued in arms, notwithstanding the surrender of Humbert. They even attacked Castlebar, but were repulsed. They were afterwards obliged to take refuge in Killala, from which, being stormed by the royal forces, they were driven with great slaughter.

The French government at last seemed as if they meant to send assistance to Humbert; and, as a prelude to this assistance, a brig arrived near the north-west coast of Donegal, where it landed its new supplies. Among these was Napper Nandy, who had been constituted general of brigade in the French service. As Tandy was soon, however, as he learned the fate of the army of Humbert, he relented. He was afterwards arrested at Hamburg by the British government, tried in Ireland, pleaded guilty, but was pardoned. Another attempt of the French to revive a cause now desperate was equally unsuccessful. A squadron, consisting of one ship of the line, and eight frigates, with troops and ammunition on board, destined for Ireland, was fallen in with off the western coast of that island by the squadron of Sir John Borlase Warren, on the 15th of October, who captured the ship of the line and three frigates. Afterwards the rest, except two frigates, were taken. Another squadron of three frigates, with 2000 troops on board, anchored in the bay of Killala on the 27th of the same month; but, on the appearance of some British ships, they set sail and escaped.

The plan of a union between Great Britain and Ireland, and, appears to have been first proposed by the Irish respecting peers, in their address to Queen Anne in the years 1703 and 1707, but at this time the British cabinet was adverse to it. Afterwards, when the Irish volunteers traversed the British government to render the Irish parliament independent of that of Britain, an union was sought for by the British, but it was no longer an object of desire among any classes of the Irish. The almost uninterrupted insurrections by which Ireland was disturbed after the commencement of the French revolution, seem to have suggested to the British cabinet the idea of seriously bringing about a union. As it was well known that such a measure, if it came unexpectedly upon the Irish unprepared for it, and strongly prejudiced against it, would not be carried without creating serious discontent, it was resolved to bring the question before the public in pamphlets, before it was agitated in parliament. Accordingly Mr. Cooke, the under secretary for the civil department, in 1798,
published *Arguments for and against a Union between Great Britain and Ireland considered.* The country was immediately most feelingly alive to the discussion of this most important question, and became divided into two parties, Unionists and Anti-unionists. On each side were found those who, on all other previous questions, had ranged themselves on opposite sides; but the majority of the people were certainly against a union. On the 22d of January 1799, the measure was recommended by the viceroy to parliament. In the House of Lords a favourable address was voted by a large majority. In the Commons, after a debate which lasted 23 hours, there was a majority of only one in favour of the measure. When it was again brought forward the next day, those who opposed the union had a majority of five. Before the conclusion of the session, however, those who were favourable to it had attained a majority; but the detail of the measure was postponed till the next year. In the British parliament the question had also been introduced during the session of 1799, and, after considerable discussion, but with less opposition than in the Irish parliament, a series of resolutions recommending a union had been voted.

When the Irish parliament assembled again on the 15th of January, 1800, a motion was made hostile to the measure, which, after a long and animated debate, was negatived by a majority of 42. On the 8th of February, Lord Castlereagh communicated a message from the Lord Lieutenant, in favour of a union, and developed the plan on which it was to be effected. On a division of the House for taking this message into consideration, there appeared 158 in favour of it, and 115 against it. The House of Peers were more decidedly in favour of a union. In it the lord chancellor, Fitzgerald, now Earl of Clare, was one of its most strenuous supporters, while the speaker of the House of Commons was strenuously opposed to it. It was also opposed by Sir Lawrence Parsons, the Duke of Leinster, Lords Charlemont and Moira, and Mr. Grattan. In order to counteract the effects of such a formidable opposition, government had recourse to those means, which the distribution of places of honour or emolument must always put in their power, and which too frequently have overcome the consciences of those who have been their most loyal in their professions of purity, independence, and patriotism. By the active and judicious employment of these means, the majority in the House of Commons had been greatly reduced, and the prospect of carrying the measure was rendered every day more favourable. Besides, many of those both in and out of parliament, who, during the first impulse of their feelings, had reproached the union, without considering the arguments that might be urged in favour of it, having become cool, and divested themselves of prejudice, resolved to support it. The arguments for and against this measure, are thus summed up by Mr. Gordon in his *History of Ireland*.

"The opponents of the measure insisted, that the representative of a nation were not vested with a power of abolishing its independence, by the transfer of its sovereignty, or right of legislative, to any foreign country; that such a transfer, without the general consent of the people, ought to be resisted, as a dissolution of the existing government, and introductive of anarchy: that a local parliament, best acquainted with the habits, prejudices, and dispositions of their fellow subjects, ever present on the spot to administer immediate relief to their wants, or guard against their excesses, was preferable to a foreign legislature, unacquainted with the state of the people, and too distant to receive information, or apply the proper remedies in due time: that the Irish members in the Imperial Parliament would become, as the Scotch in that of Great Britain had become already, the tools of administration, to the increase of the undue influence of the crown: that the evil of absences would be nearly doubled, to the intolerable augmentation of the exhausting drain of money, and the abandonment of the tenantry to the tyranny of agents, who would abuse their delegated power to the gratification of their pride and avarice: that, by the absence of the bishops from their dioceses, in consequence of their affection upon the Imperial Parliament, the inferior clergy would be neglected, to the growth of irreligion, and the discouragement of literature: that the national importance of the Irish would be annihilated by the degradation of their country from the rank of a kingdom: and that whatever concessions should, in return for her sacrifices, be made to Ireland in the compact of union might at any time afterwards be cancelled by the Imperial Parliament, from its vast majority of English members."

"The advocates of the incorporating system contend, that in every government is inherent a despotic power for the maintenance of order, the enacting of laws, and for the making of alterations occasionally in its own constitution, for its adaptation to successive changes of circumstances, which in the course of human affairs inevitably take place: that this power is lodged, according to the British system, conjointly in the king, the lords, and the representatives of the people: that the modification now proposed, was no surrender of independence, but an intimate conjunction with the sister island, on honourable terms,—no subversion, but a change of the constitution: that, to deny the competence of parliament for the effecting of this change, would be to deny the validity of the act by which England and Scotland had been incorporated, and consequently to deny the right of his present Majesty to the crown of the united kingdom, which was founded on the 2d article of that act: that otherwise than through their representatives in parliament, the consent of the people could only be collected from the opinions of the well-informed, the reflecting and disinterested part of the nation: that the measure proposed was an act of desire: that, whatever might be the advantages to Ireland from her local parliament, the disadvantages were far greater: that the feeble bond, by which the two kingdoms were connected, was in danger of being broken by a disagreement of the two legislatures, of which an alarming instance in the appointment of a regent had lately occurred: that by the distinctness of her legislature, Ireland was excluded from commercial advantages, as had appeared in the case of the commercial propositions, which had been rejected from political jealousy arising from this distinctness: that this boasted national parliament was founded on no national basis, but on the pretensions of a few to a monopoly of the government, and resources of the whole,—a puny and precarious oligarchy, who considered the nation as their private property, and were ready to sacrifice the public peace and happiness, to the insatiate love of patronage and power: that for the demolition of this oligarchical tyranny, and the curbing of violent factions, by which the nation was distracted and oppressed, recourse should be had to a legislature superior to local prejudices, and remote from the baneful influence of party: that the Irish members in the imperial parlia-
ment could not be tools of the minister in a higher degree, nor with more expense to the nation, than the local parliament had already been, in which were 116 placemen and pensioners: that the augmentation of the evil arising from the absences, would be more than counter-balanced by new advantages, particularly those of commerce: that the persons who now made the increase of absences an argument against the union, had not long before opposed the design of a remedy for this evil, the proposal of a tax on absences, which administration had offered to support: that the necessary absence of bishops from the clergy under their care, by their attendance in the Imperial Parliament, would occur so seldom, as not in the slightest degree to prevent them from performing their duty in rewarding merit, if such should be their inclination: that the political amalgamation of the Irish with the people of Great Britain, could not be a declension from national dignity: and that the infraction of the compact with Ireland, could not with more reason be apprehended from the Imperial Parliament, than the disfranchisement of Scotland, of Wales, or of Yorkshire.

On the 21st of May, on a motion that leave be given to bring in a bill for the union into the House of Commons, there were 160 for it, and 100 against it. On the second reading of the bill, on the 26th of the same month, Mr. Grattan moved to defer the business till the 1st of August; but only 87 voted in support of this motion, and 124 against it. On the 4th of June, the bill passed the committee. In the House of Lords, where there was less opposition, it was read a third time on the 13th of June. The subject being again introduced into the British Parliament, it was discussed in both Houses; and on the 2d of July received the royal assent.

The articles of union were partly commercial, or relating to revenue, and partly political. The regulations of commerce did not materially differ from the propositions of 1785. The proportion of revenue to be raised in the two kingdoms, was fixed by a comparison of their aggregate exports and imports, and their consumption of certain kinds of merchandise. By this rule, Ireland was to raise two parts of the revenue, for every fifteen raised by Great Britain during the first twenty years after the union. At the termination of this period, the proportion was to be regulated by parliament. One hundred commoners from Ireland were to sit in the imperial parliament, two for each county, two for each of the cities of Dublin and Cork, one for the university, and one for each of the 31 most considerable towns. The proprietors of the disfranchised boroughs were to receive a pecuniary compensation. Four lords spiritual, by rotation of sessions, and 25 lords temporal, elected for life by the Peers of Ireland, were to sit in the House of Lords. The first of January 1801, was fixed as the commencement of the union.

From the period of the union, the history of Ireland naturally falls into that of Britain; but we shall here cursorily notice such transactions or proceedings in the Imperial Parliament, as more directly relate to this country.

In the first session of the Imperial Parliament, a bill was passed for indemnifying all persons concerned in the securing, imprisoning, and detaining individuals, under the suspicion of the habeas corpus act, or in the performance of any acts done for the preservation of the public peace, and suppression of rebellions and insurrections in Ireland, since March 1798. Ireland appeared to be gradually subsiding into a state of comparative tranquillity, when, in the summer of 1803, it was suddenly agitated by a considerable though short lived alarm. The constitution was attempted to be subverted by the violence of a few men, the rashness of whose attempt was severely paralleled. The leaders were Robert Emmett and Thomas Russel, both of whom had experienced the clemency of government in 1795; the latter was brother to the Emmett who was one of the directory at that period. The centre of the plot was Dublin, where these men had collected a few arms, and hoped, by the assistance of a mob, to seize the castle, which was protected by upwards of 2000 soldiers. The 22d of July was the day fixed upon for the insurrection. On the morning of that day a crowd of country people from the county of Kildare entered the capital; a signal was given by the firing of rockets, and the doors of the depot of arms were opened. The number of the insurgents is supposed to have been about 500. The time of their principal operations was late in the evening; and while the mob were the most furious, they met Lord Kilwarden, the lord chief justice of the King’s Bench, his daughter Miss Wolfe, and his nephew Mr. Wolfe. The two gentlemen were dragged from their carriage and murdered. Miss Wolfe effected her escape, and fled to the castle, where she gave the alarm. Their only retaliated effort was an attack on an outpost, defended by a few soldiers, whom they overpowered and put to death. But being themselves attacked by about 120 soldiers, they were dispersed in a short time, and the whole insurrection was extinguished. Emmett, Russel, and some others of the leaders, were tried, condemned, and executed. A royal message was sent down to parliament, announcing the insurrection and its end, in which it was recommended that measures should be taken for the suppression of the rebellious spirit, from which the insurrection had originated; and a bill for trying the rebels in Ireland by martial law, and another for suspending the habeas corpus act were passed. Emmett, Russel, &c. were however tried, not by a court martial, but a special commission.

As the spirit of insurrection still lurked in various insurrectionary parts of the country, and broke forth in various acts of outrage, in 1807, Sir Arthur Wellesley, who was then secretary to the lord lieutenant, moved, in the House of Commons, for leave to bring in a bill, the provisions of which were the same with those of the insurrection act of 1796, so far as they gave power to the Lord Lieutenant to proclaim disturbed counties, and authority to the magistrates to arrest persons found out of their dwelling-houses between sunset and sunrise; but it was enacted, that persons so arrested should be tried at the quarter sessions by the magistrates and assistant barristers, with the addition of a king’s counsel sent for the purpose. Another bill was passed to prevent improper persons from keeping arms. These bills were opposed strongly, but their necessity was admitted by Mr. Grattan.

It had been generally understood, that, in the event of the union between Great Britain and Ireland taking place, the Catholics might look forward to the removal of all the disabilities under which they still laboured; their emancipation, however, not taking place, they resolved to endeavour to bring it about by every peaceable and legal method. That they might act with more effect, as well as with less trouble to themselves, a committee was formed; the deliberations of that of 1809, were always confined to their petition,
Ireland.

and the members had declared their resolution not to transgress the convention act, by any thing like delegation; the government of course did not interfere with them. But it was alleged that the committee of 1810 acted upon very different principles; it called an aggregate meeting of the Catholics, which came to the resolution, that the committee should have the power to manage, not merely the Catholic petition, but the Catholic affairs generally. A committee of grievances was afterwards appointed, which met weekly, and imitated all the forms of the House of Commons. Government took the alarm, and even some of the most respectable Catholics thought that the committee, by proposing a delegation of ten members from each county, had exceeded its powers. A circular letter from Mr. Wellesley Pole, secretary to the Lord Lieutenant, was addressed to the sheriffs, and the chief magistrates of all the counties in Ireland; they were required, in pursuance of the convention act, to cause to be arrested, and committed to prison, unless bail should be given, all persons within their respective jurisdictions, who might be guilty of having been in any way concerned in issuing notices for such election or appointment; or of having attended meetings for such purpose. Before this letter was written, the opinions of the Lord Chancellor, and the Attorney and Solicitor General had been taken; and the letter itself had been drawn up by the Attorney General in such a manner as he hoped would bring closely before the eyes of the Catholic committee the tendency of their proceedings to violate the convention act. This letter was dated the 13th of February 1811, and, on the 23d, two magistrates of Dublin were directed by the Lord Lieutenant in council, to repair to a house where the Catholic committee assembled. This they accordingly did; and Lord Ffrench, who was in the chair, demanded by what authority they entered the room? the answer was, that, by order of government, they were come to disperse the meeting, as, being a meeting of the Catholic committee, it was illegal. After some conversation, the particulars of which are differently related, one of the magistrates went to consult Mr. Wellesley Pole; and, on his return, he said, that as Lord Ffrench had given them an assurance that it was merely a meeting of Catholic gentlemen for the purpose of signing a petition to parliament, and not a meeting of the Catholic committee, government had given directions that it should not be interrupted. The letter of Mr. Pole was made the subject of some conversation in parliament; and afterwards motions were made in both Houses for the production of copies of all the dispatches to and from the Lord Lieutenant, relative to this business, which were negatived.

On the 20th of May, the petition which the Catholic committee had drawn up, was presented to the House of Commons by Mr. Grattan; on the 31st he moved that it should be read, and also the votes of the House, conveying thanks to the armies under Lord Wellington and General Graham; from these he took occasion to point out, with great eloquence and force of argument, the claims of the Irish Catholics—of those men who had contributed so essentially to achieve those victories, by which the glory of Britain had been so highly exalted, and the safety and independence of Europe so essentially benefited. On a division, there appeared for the motion 83, and against it 146. The Catholic petition was also introduced into the House of Lords by Lord Donoughmore, who moved that it should be referred to a committee. This motion was negatived by 121 to 62.

The Catholics of Ireland were not cast down by the result of the motions respecting their petitions; nor were they intimidated by Mr. Wellesley Pole’s letter, and the measures of government thereupon. On the contrary, they resolved to persevere with increased zeal and assiduity in nominating delegates. On the 9th of July, an aggregate meeting was held at Dublin, for the appointment of delegates to the general committee of Catholics, when five persons were apprehended by a warrant from the Lord Chief Justice, for a breach of the convention act. One of them, Dr. Sheridan, was brought to trial; but the jury brought in a verdict of not guilty, upon which the Attorney General declined prosecuting the others. The verdict gave great encouragement to the Catholics, as well as great satisfaction to many Protestants, not only because they were friendly to the claims of their Catholic brethren, but because an attempt had been made and defeated, of perverting the law to the violation of the liberty of the subject. On the 19th of October, nearly 300 gentlemen, who formed the new committee of delegates, held a meeting, at which a petition to parliament was read and approved. The police magistrates did not arrive till the meeting was broken up; but on the second meeting of this committee, on the 23d of December, it was dispersed by a magistrate. On the 26th of the same month, the aggregate meeting was held, when the proceedings of the Irish government were severely censured; and it was resolved not to submit to them in silence. The only other circumstance relating to the history of Ireland that took place this year deserving of record, was an act passed, to enable the crown to interchange the militiamen of Great Britain and Ireland. In this act was a clause, to confer on the Irish Catholics serving in England, all the civil, military, and religious exemptions which they enjoyed in Ireland.

Early in the session of 1812, the claims of the Irish Catholics were again brought under the discussion of both Houses of Parliament. On a subject so frequently examined, little or no novelty could be brought forward. It may be mentioned, however, that the Marquis of Wellesley and Mr. Canning, though they professed themselves decidedly convinced that the claims of the Catholics were supported by justice and policy, yet were averse to conceding them while they were demanded in such a menacing attitude. The motions were lost in both Houses; but, in the House of Commons, the majority seemed on the decline.

From this circumstance the Catholics took heart. The tables of both Houses of Parliament were loaded with petitions both for and against their claims. On the 25th of February, 1813, Mr. Grattan moved for a committee of the whole House of Commons, to take into consideration the state of the laws that affected his Majesty’s Roman Catholic subjects in Great Britain and Ireland. On a division, the motion was carried by a majority of 40. A committee was then formed, when Mr. Grattan moved, that the Catholic disabilities should be removed, and that the establishments in church and state ought to be effectually secured. The first motion was carried by a majority of 67. On the 30th of April, Mr. Grattan introduced a bill, which enacted, that it should be lawful for persons professing the Roman Catholic religion, to sit and vote in either House of Parliament, provided they took a prescribed declaration or oath, instead of the oaths of allegiance, abjuration, and
IRELAND.

1814, when a set of banditti, called Carders, committed outrages in some parts of the country. They were so called, because they tortured those who had incurred their hatred by the application of wool-cards to the skin and flesh of their victims. In consequence of their outrages, an act, to be in force for three years, was passed, similar to the insurrection act of 1807. The proceedings of the Orange societies, which at this time were very numerous, and by no means actuated by a liberal or conciliating spirit, were strongly reprobated in parliament during the discussions on this act.

In 1816, Ireland suffered, in common with Great Britain, and nearly the whole of Europe, from the effects of a season almost unprecedented for coldness and rains, and for a most scanty produce of grain; but though there was a nearer approach to famine in Ireland than in any part of Britain, and though this calamity pressed most heavily upon the inhabitants, from their not possessing those resources, either of trade or poor-rates, which are open to the lower classes in England, yet Ireland was quiet and loyal, while England was agitated by the most outrageous attempts against the public peace. See Leisl's History of Ireland; Gordon's History of Ireland; Gordon's History of the Rebellion in Ireland; Annual Register; Aikin's Annals of George III.

PART II. STATISTICS OF IRELAND.

CHAP. I.

IRELAND, called by the inhabitants Erin, and by the Welsh Yverdon, lies in the Atlantic Ocean, between 5° and 10° 40' West Longitude, and 51° 12' and 55° 13' North Latitude. It is separated from Great Britain on the east by the Irish Channel, which is also called St. George's Channel; the latter appellation, however, is more commonly and particularly given to the southern entrance; and the northern entrance is, strictly speaking, distinguished by the appellation of the North Channel. The Atlantic Ocean bounds it on all the other sides. The nearest land to it on the west is America; on the south, Galicia in Spain; and on the north, the Hebrides. The Irish Channel varies very much in breadth; generally speaking, it is narrowest at the two extremities, and broadest in the middle; the least breadth is between the Mull of Kintyre, in Argyshire, and Torhead, in the county of Antrim; the distance between these two places is about 16 miles.

Ireland is of an oblong shape, which, however, is bent from a straight line by the province of Munster; for this province, instead of stretching itself first from the north to the south, and then from the south to the west, like the rest of the island, runs, in a sloping direction, from north-east to south-west, and its western shores stretch farther into the sea than any other part of Ireland. Although Ireland is more compact in its form than Great Britain, yet it is still irregular, narrowing from the middle, with various inequalities to the north-east and south-west; 'contracting suddenly in the former direction, and then somewhat dilating, so as to make in that quarter a rounded peninsula; in some degree gibbous on the south-east, and of a serrated form on the south-west.'

From this account of its figure, it will be evident that its greatest length must be from the north-east to the south-west; a line drawn between the two most distant points in these quarters, viz. Fairhead in the county of Antrim, and Mizenhead in the county of Cork, will measure 241 Irish, or rather more than 306 English statute miles. From Enniskerry, in the county of Mayo, to Carnsore-point, in the county of Wexford, is the greatest breadth of Ireland, being 163 Irish, or 207 English miles. The greatest length that can be drawn along a meridian, however, is not more than 185 Irish, or 225 English miles; and the greatest breadth that can be measured nearly on a parallel of latitude, is not more than 157 Irish, or 194 English miles. In consequence of the numerous and deep indentations of the sea on the west coast, there is not a spot in the kingdom 50 miles distant from the sea.

Geographers differ with regard to the superficial Area, contents of Ireland. Dr. Beaufort, from a computation made by carefully measuring the area of each county, on the best maps, is of opinion that it contains considerably more than 18,750 square miles, or several thousand acres above 12 millions, Irish measure, which is equal to 50,870 English miles, or 19,436,000 English acres. Mr. Wakefield is of opinion that, including the inland lakes, the superficial contents amount to 32,901 English square miles, of 69° 15' to a degree; or 12,722,615 Irish acres, or 20,437,974 English acres. Mr. Pinkerton, and some other geographers, reduce its contents below those assigned to it by Dr. Beaufort and Mr. Wakefield, and assign it only 27,447 square miles. According to others, its contents amount to 11,067,712 Irish, or 17,927,864 English statute acres.

The progressive geography of Ireland presents little Progressive geography.
IRELAND.

Cavan, Cavan, the county town, Killshandra, and Virginia; in Monaghan, Castle-Blaney, Carrickmacross, Clones, and Monaghan, the county towns.

Leinster, which is the most eastern province of Ireland, is bounded on the north by Ulster, on the east and south by St. George's, or the Irish Channel, and on the west by the province of Munster; it contains 7360 English square miles; and comprises the following 12 counties:

In the province of Leinster, the principal places are: in the county of Louth, Drogheda, Carlingford, Dundalk, Ardee, and Louth, the county town; in East Meath, Trim, the county town, Navan, Kells, Athboy; in Dublin, Dublin, a city, the county town, and the capital of Ireland; besides it there is no place of importance in this county; in Wicklow, Bray, Arklow, and Wicklow, the county town; in Wexford, Wexford, the county town, New Ross, and Enniscorthy; in Kilkenny, Kilkenny the county town, Callan, Innistioge, Thomas Town, &c.; in Carlow, Carlow, the county town, and Tullow; in Queen's County, Maryborough, the county town, Portarlington, and Mountmellick; in King's County, Philipstown, the county town, Tullamore, Balliboy, Banagher, and Bier; in West Meath, Mullingar, the county town, Athlone, and Fore; and in Longford, Granard, Longford the county town, Edgeworthstown, Ardagh a city, Colehill, and Lanesborough.

Connaught, the most western province of Ireland, is washed on the south and east by the Shannon, and on the west by the Atlantic, and it is bounded on the north by the province of Ulster; its area comprises 7191 English square miles; and it comprehends the following five counties: viz.

In the province of Connaught the principal towns are the following; in the county of Galway, Galway, the county town, Tuam a city, Loughrea, Aghrirm, Clifden a city; in Mayo, Castlebar the county town, Mayo, in Sligo, Ballymote, and Sligo the county town; in Leitrim, Carrick-on-Shannon the county town, Leitrim; in Roscommon, Tuuls, Abbeyboyle, Ballynasloe, and Roscommon the county town.

Munster, the most southern province in Ireland, is bounded on the north by Leinster and Connaught, and on the east, west, and south by the ocean; it was formerly subdivided into Desmond, or South Munster, Ormond, or East Munster, and Thomond, or North Munster; its area occupies 9276 English square miles; and it is divided into the following six counties, viz.
In the province of Munster, the following are the principal places; in the county of Cork, Cork the county-town, and a city, the second place in size and population in the kingdom, Bandon, Baltimore, Youghall, and Rathcormuck; in Kerry, Listerwell, Ardfert, the county-town and a city, Tralee and Dingle; in Clare, Killaloe a city, Ennis, or Clare, the county-town, and Kilfinora; in Limeric, Limeric the county-town and a city, Castle Connell, Charlesville, Killmallock; in Tipperary, Cashel the county-town and a city, Tipperary, Nenagh; and in the county of Waterford, Lismore, Dungarvon, and Waterford, the county town and a city.

Few of the places above enumerated are of considerable size; so that, if we except Dublin, Cork, Belfast, Limeric, Galway, Sligo, Londonderry, Dundalk, Newry, Waterford, Wexford, Kinsale, Kilkenney, and a few others, the rest can only be considered, in respect to size and population, as villages. It may be remarked, with regard to the towns of Ireland, that, with scarcely a single exception, all the places of even tolerable size and population, have a near and easy communication with the sea. The chief towns in the interior are rather venerable for their ecclesiastical antiquity than important in themselves: Kilkenney is an exception.

From these Tables it will be seen that the largest of the provinces is Munster, and the smallest Connought; and that the largest county is Cork, and the smallest Louth: it may also be remarked, that Leinster contains a far greater number of parishes in proportion to its area than any of the other provinces, which circumstance arises from its having been first colonized and civilized by the English, and to the consequent increase of its population: a similar effect was remarked under the statistics of England, with respect to Norfolk and some other counties in that kingdom. The parishes are subdivided into townlands, and ploughlands, greeves, cartons, &c.

The greatest elevation of the soil, or platform of Ireland, is in the Bog of Allan. This elevation does not exceed 270 feet, yet it is sufficient to give descent to the greatest rivers in the island. The ridge, or back-bone of Ireland, runs through this bog, dividing the waters of the Shannon from those which flow, in an easterly direction, to the Irish Channel, and southward to the shores of Munster. This elevated ground is connected with the principal mountains of Ireland, winding on the north to those of Tyro, and on the south to those of Sleevel Bloom and the Galtees, and afterwards turning to the west, to the peninsula of Corcaighouny.

Ireland is by no means a mountainous country; for though there are many hills of considerable elevation, yet neither their height, their continuity, or their number can give it that character, compared with those countries which are generally deemed mountainous. Many parts are level, some quite flat, and many uneven with hills of no great magnitude; on the other hand, there are not any such low fenny flats as in Britain. According to Dr. Beaufort, in his Memoir of a Map of Ireland, the most extensive levels are about the middle of the island, where a vast plain stretches quite across from the east sea, from the mouth of Dublin Bay to the mouth of Galway, including in its extent the Bog of Allen. In general the maritime parts, particularly the western, are more mountainous than the interior, yet the mountains are so disturbed that we find few places in which, (to use this author’s expression,) the prospect is not somewhere terminated by this species of majestic scenery, forming a back ground, seldom more remote than 20 miles.” The Irish mountains in general form short lines or detached groups, as they are in unconnected masses of different magnitudes; in general they are of easy ascent, and admit of culture a considerable way up their sides; some of them, however, are precipitous, terminating in cones or spires. On the west and south of the Lake of Killarney; there is a chain of considerable height; one of which, Mangerton, is, according to Kirwan, 2693 feet above the level of the sea. On the north-west of Bantry Bay, there is a small chain which stretches to the east. To the north of this is the chain of mountains called Sleevel Bogher and Nagles, followed by the Galtee mountains; on the east of the province of Munster, the mountains of Knockaddown bend in a southerly direction to the bay of Dungarvon. In the interior of the province of Leinster, the Sleevel-bloom mountains divide the King’s and Queen’s counties, and form a great chain; in this province also lie the Wicklow mountains, which are about 30 English miles in length, and 12 in breadth. In the south-east corner of the province of Ulster are the mountains of Mourne; one of them called Sleevel Donaw, in the county of Down, is said by Kirwan to have an elevation of 2999 feet above the level of the sea. The centre of this country is formed of the mountains of Sleavecroob. The extreme western peninsula of Connaught is one of the most mountainous regions of Ireland. In the county of Mayo, there is a solitary hill, called Mount Neagh, that, according to Kirwan, is 2630 feet above the level of the sea. Crouch Peak, in the same county, on the south-east of Clew bay, rises to the height of 2660 feet.

With the exception of the Shannon, Ireland possesses no very considerable river. The Shannon, which is not only the largest river in this country, but one of the finest in the British isles, rises in the county of Leitrim. After running a few miles, it spreads into Lough Allen; from this lough it issues in a much fuller stream than it entered. After a progress of several miles, it again expands its waters, and assumes the name and form of Lough Ersk; this lough, however, though long, is not very broad. On its exit from this, it forms another lake, called Lough Ree, 15 miles long and 5 broad; afterwards it appears a large and beautiful river. Between the counties of Tipperary and Clare, it expands, and forms Lough Der, or Derke, 18 miles long and 4 broad. On leaving this its stream now of very considerable volume and rapidity, flows for several miles, and at length falls into the sea, about 50 miles below Limeric, at a place called Knockpatrick; below this city, it expands into a vast estuary from 3 miles to 10 in breadth. The whole course of the Shannon is about 170 miles; and it is nearly 7 miles broad at its mouth; in its course it divides the pro-
IRELAND.

The River Bandon, as succinctly and well described by Spencer, is

"The pleasant Bandon, crowned with many a wood."

This river, which was anciently called Glashine, rises in the mountains of Carberry; passing by Dunmanway, and having a tributary stream, it runs to the east through a bog, with a divided channel, and arrives at Inskeen: after passing the town of Bandon, it winds north-east to Innis-shannon, a little below which it becomes navigable. Hence it winds in several beautiful reaches to Kinsale. The Lee rises out of a lake in the west of Muskerry; and after passing by several hills, and receiving a considerable accession of water, it expands into Lough Alla; on its exit from this, it flows to Cork; a little below this city, being joined by the Glannire, it expands into a spacious and commodious haven, falling into the sea about 15 miles below Cork; it is not navigable any higher than this place.

The Blackwater, or Broadwater, rises in a bog near Castleisland in the county of Kerry; its course is nearly due east for about 50 miles, till it comes to Cappoquin; here making an angle, it turns to the south, and proceeding in a straight course, about 10 miles farther, it falls into the sea at Youghall; it is at present navigable only as high as Cappoquin for vessels of any burden, but formerly it was navigable as high as Mallow, about 40 miles from its mouth. This river is very liable to overflow its banks. The Bandon, Lee, and Blackwater, are all in the county of Cork, and run in a manner parallel to one another; the Bandon, about 7 miles south from the Lee, and the Blackwater, 14 miles to the north of that river.

The Sure rises at the foot of Banduff mountains in the county of Tipperary, near the source of the Nore; but they soon take different directions: the course of the Sure is at first south-west; afterwards due south; below the village of Ardfinnane, it turns to the east, dividing the counties of Tipperary and Waterford; and having received a small stream, it bends northward till it reaches Spencer's "Sweet Clonmel," after a progress of 8 miles more it comes to Carrick, and at last falls into the sea at Waterford: it is navigable for large vessels as far as this city, and for barges as far as Clonmel. The Barrow rises in the King's County; its course for a short space is north-east, then suddenly turning, it flows to the south-east, dividing King's and Queen's Counties from that of Kildare: it next passes through the centre of the county of Carlow, and then separates the counties of Kilkenny and Wexford; a little before it reaches Ross, it receives the Nore, already mentioned; after their junction, its course bends rather to the west, till it unites with the Sure, forming the right arm of Waterford haven. The Nore is navigable from New Ross to Inistioge; the Barrow and the Nore, previous to their junction with the Sure, are navigable for large ships to New Ross, and for barges to Carlow and Athy. After the junction of all these three rivers, there is a considerable bar, which prevents the passage of large ships, except during high tides.

The Slane rises in the south-west corner of the county of Wicklow; its course at first is very winding through the county of Carlow, sometimes to the south-east and sometimes to the south-west; afterwards, flowing in a south-east direction, it divides the county of Wexford till it reaches Enniscorthy; its course is then south, and afterwards east, which brings it into a bay a little below the town of Wexford. The Slane is navigable for barges from Wexford for Enniscorthy. The river Liffy rises about 10 miles south-west from the city of Dublin, and about 15 west from the sea: its course at first is south-west through the county of Wicklow; then running directly west, it enters the county of Kildare; where it again forms an elbow and flows north-west, and at length due north: in this part of its course, it is parallel to the sea, and nearly 30 miles distant: afterwards bending to the north-east, it enters the county of Dublin, and then turning at first to the north and next to the east, it flows with a full stream and pretty strong current to the capital, and falls into the Bay of Dublin; its course is about 50 miles.

The Boyne rises in King's county; by its junction, after its rise, with a great many rivulets, it becomes a very considerable river in its passage through the county of Kildare; and still stronger in its course, and more beautiful in its scenery, when it enters East Meath, where it passes by Trim, Navan, and Slane; its course from Slane to Drogheda, for about seven miles, is east; about two miles below Drogheda, it falls into the sea. The Boyne is navigable for ships of considerable size as far as this town; and, by means of cuts, barges may proceed from Drogheda to Navan. The river Bann rises in the plain called the Deer's, or King's Meadows, in the northern part of that ridge of mountains, in the county of Down, already mentioned, called the Mourne; it soon becomes a large stream; its course at first is winding, but generally in a direction to the north-west; at Portodown, it is joined by the canal of Newry; and, a few miles lower down, it falls into Lough Neagh at Banfoot-ferry, after running about 30 miles. When it leaves this lake, it continues its former direction north-west, and divides the counties of Antrim and Londonderry. After passing over a ridge of rocks, called the Salmon leap, it flows with impetuous force into the sea, a few miles below Coleraine. The river Foyle passes by Londonderry, and has a considerable estuary called Lochfoyle; it is navigable to Lifford.

Ireland abounds in lakes, some of which are very extensive. They are commonly divided into salt water lakes, and fresh water lakes; but as the former, properly speaking, are estuaries, or inlets of the sea, they will be described afterwards, when we treat of the sea coast of Ireland; at present, we shall confine ourselves to the fresh water lakes, or lakes properly so called.

The most extensive lake of fresh water is that of Erne. Erne, which, however, sometimes appears as a river, and sometimes as a lake. Lough Erne is in the province of Ulster, and county of Fermanagh; as a river,
it derives its source from a small lake on the borders of the county of Longford. Below Belturbet, it expands itself into a lake; it again assumes its former shape, and flows past Enniskillen; between this place and Church-hill, it is sometimes a lake and sometimes a river; but a little to the south of Church-hill, it widens into an extensive lough, appearing like an inland sea. From this description it will be seen, that Lough Erne, properly speaking, consists of two loughs, north and south, joining the other, which lies east and west, by a small canal; and from this last the river Erne runs into the sea; the first of these loughs is 20 miles long, the other about 15; the greatest breadth of Lough Erne is 12 miles; its medium breadth 10 miles. This lough contains, in its two basins, 300 or 400 islands.

Next in magnitude is Lough Neagh, which lies in the centre of the province of Ulster, and is bounded by five counties, Antrim on the south, Tyrone on the west, Londonderry on the north-west, Antrim on the north and east, and Down, which barely touches it on the southern east angle. It was formerly believed that Lough Neagh covered 100,000 acres of land, and it is so laid down in all the old maps of Ireland; but, by a recent accurate survey, its area is reduced nearly to one half, as it does not exceed 50,000 acres; its length is 15 miles, and breadth seven miles. This lough is supplied by the constant influx of several rivers of considerable magnitude, although there is but one narrow channel by which these are again discharged, yet it very seldom inundates its shores. The river Bann, through which its waters find their way into the ocean, has been already described. In some places, the coast of Lough Neagh is bold and abrupt; but in general it is flat, and nearly bare of wood; nor are there in it any of the delightful intermissions, for which Lough Erne and Killarney are celebrated; there being no breaks in the prospect, with rocky and wooded islands. The tameness of its surface is broken only in two parts, by Black-water island, in the south-western angle of the lough, at the mouth of the river of the same name, and by Ram Island, on its eastern borders, near the coast of Antrim. Lough Corrib, in the province of Connaught, and county of Galway is next in size to Lough Erne and Neagh; it is 21 miles long from north to south, and at the upper end broad, but grows narrower, so that its medium breadth is only about four miles. In the midst of the mountains of the county of Kerry, is the celebrated Lakes of Killarney: they are three in number; the largest, which is called the lower lake, occupies an area of 8000 acres; its south-west shore is bounded by a majestic range of mountains, while, on the opposite shore, there is the fine and striking contrast of flat land, in a high state of cultivation. Mucross Lake, to the south, occupies 640 acres: it lies immediately under the Turc mountain. For about three miles, the lakes continue with a width which gives them the appearance of a river; till they approach the upper lake, containing 720 acres. As this lake lies in a hollow, among stupendous mountains, its scenery is magnificent and sublime in the highest degree. These glassy lakes, overlooked by stupendous mountains; bordered with pendent woods, most delightfully variegated, ornamented with the most romantic verdant islands, resounding on all sides with waterfalls, and the reverberations of a vast variety of echoes, combine an assemblage of beauty, perhaps unparalleled,—at least far surpassing all power of language to express." The lakes are almost the only ones in the south of Ireland; in the east, there are none of any importance; on the north-west are the lakes of Gask, Frierty, Melno, Gill, and Macnenn. Lough Allan, is in fact the river Shannon under another name, and has been already described.

The water-fall at Hungra-hill, in the county of Cork, may aptly be mentioned in this place; it is thus described by Dr. Smith, in his Ancient and Present State of the County of Cork. "Not far from Ross-Mac-Owen, is one of the largest and highest water-falls in this kingdom. This cascade is very visible from the town of Bantry, at least 14 miles distant from it. The water is collected from various small rivulets and springs, forming a large lake on the top of a vast, high, rocky, and almost perpendicular mountain, called Hungra-hill, which is at least 700 yards above the level of the bay of Bantry. The water cascades from the top of this mountain, in a beautiful sheet, at least 10 yards broad, which expands as it falls; about half the height of the mountain, it dashes perpendicular on a prominent rock, from whence a mist arises, almost the third part of the hill, which, in some particular stations, the sun's rays playing upon it, and meeting the eye of the spectator, must make a charming appearance; these kinds of mists, in such positions, generally reflecting the colours of the iris: Hence it falls from rock to rock, till it has passed the rugged declivity of Hungra-hill; and, before it joins the ocean, it has another fall, cascading in an arch over a lower hill,—all which make a fine sight as one sails up and down the bay." Not many years after the example set by the Duke of Bridgewater, a great canal was begun from the city of Dublin to the river Shannon; but, in the original plan and survey, great errors were committed, and the work was interrupted in the year 1770, after the canal had been carried to the Bog of Allan, at an expense of £77,000. At the time of the Union, £500,000 was voted by government to assist the completion of this and other canals in Ireland; and the grand canal now extends from Dublin to Shannon harbour, while another branch proceeds to Athy, where it joins the Barrow; its greatest utility is to supply the capital with turf. The royal canal, one branch of which begins at Glassmanagore, in the county of Dublin, and the other at the Liffy, near the Lots, extends to Coolmackin beyond Mullingar; it is principally used for the carriage of corn and turf. The Newry canal, which runs along the southern boundary of the county of Down, is one of the most useful in the kingdom. The improvement of agriculture, and the conveyance of coals from the Tyrone coaling stations, suggested the execution of this canal; it is cut from Carlingford Bay, and, joining the Newry water, embraces the upper Bann at Portadown; thus continuing the navigation to Lough Neagh, while a branch strikes off to the Tyrone coaling stations. This canal carries vessels of 50 or 60 tons burden. The navigation of Lough Derg, above Killaloe, of the Shannon from Lough Ree, and of the Barrow from Athy, has been improved, by directors appointed under an act of the 43d of George III.

Ireland has a circuit of 250 leagues of coast, which is deeply indented, particularly on the west and southwest, where the whole force of the Atlantic ocean, swelling to a tremendous height, and breaking with inconceivable violence on its shores, forms in the deep recesses of the promontories, by which these coasts are distinguished, some of the noblest havens in the world. Fourteen harbours for the largest ships, seventeen for frigates, and thirty-six for coastering vessels, besides twenty-four good summer roads, are to be found on the different coasts of Ireland.
In the description of this coast, we shall begin with the province of Munster, proceeding by the south and east coasts to the north point of the island. The coast of the county of Clare, extends from Galway Bay to the Shannon; in this extent there are several bays, but none of them form a good harbour. The mouth of the Shannon is formed by two promontories; that on the north is called Cape Leane, or Louispean; that on the south Ballyleigh, or Kerryhead. On the Kerry side, about 25 miles from the sea, lies the Tarabet, a small but very safe and commodious bay, behind a little island. Without the mouth of the river, round Kerryhead, there is a large body of water, one side of which is called Ballyleigh, and the other Tralce Bay. Near this part of the coast are many sand hills, formed by the wind, and on some parts the sea gains rapidly; other parts of this coast present to view some of the highest mountains in Ireland. The peninsula of Dingle is of great height, and behind it rises Brandon hill, a noted land-mark, 2250 feet high. Brandon Bay derives its name from this hill: many of the cliffs that line this part of the shore, are worn into deep and extensive caverns. On the east is flat low land, off which are seven small islands called the Hogs. On the north side of the peninsula of Dingle, is the harbour of Smerwick, corrupted from St. Mary Wick's Bay; it lies from north to south, is deep and sheltered from all winds but north and north-west. Between this harbour and Ferriter Cove the land is low, and has been much covered with sand by the sea and wind. Dunmorehead is the west point of the peninsula of Dingle, as well as of Europe: off it lies the Blasket Islands, 12 in number; the largest of which is a great mountain, three miles long, and one broad: tradition reports that it was formerly joined to the mainland. The sound between it and the mainland is of great depth, occasioned probably by the currents of both ebb and flood setting through it with great rapidity. Fintry Bay is open, and much exposed to southerly winds: half a league to the east of Fintry, lies Dingle harbour, six leagues deep and four wide; the entrance is scarcely a quarter of a mile broad; the depth of water is 30 feet, and it is landlocked from all winds. The Isle of Valencia lies on the south side of it. The rocks called the Skelligs lie to the south-west of this island, and 12 miles from the mainland; they are of large rocks: the great Skellig rises in two pyramids of naked grit-stone, united by a space of three acres of flat ground. Kenmore river is an inlet of the sea, ten leagues long and three broad. We come next to the shores of the county of Cork. Dursey island, off the south point of the entrance of Kenmore, is four miles long and one broad. Bantry Bay forms one of the most secure and commodious harbours in the world, being nine leagues long and two broad, and surrounded by stupendously high rocky shores, with few intervals of beach; nearly in the middle is Bear-island, six miles long, rugged and barren; but forming between it and the north shore the harbour of Bearhaven, fit for the largest fleets. At head of the bay is Whiddy island, also forming an excellent harbour. On the west side of Bear-island, the passage between it and the mainland is about one mile broad; the passage on the east is something broader: immediately before the island there is from ten to six fathom water, in the east passage from thirty to forty; and further up the bay, near the isle of Whiddy, from fifteen to twenty-five. Between the south side of this island and the mainland, is the road for ships, with a depth of from twenty-four to forty feet. The tides move very gently in and out through the whole bay. Dunmanus Bay is separated from that of Bantry by a peninsula, of which Sheepshead is the promontory; the south point of the bay is formed by Three-Castlehead; this bay runs far up into the country, and is easy of entrance. The promontory which forms its west side terminates in a kind of half-moon, of which Three-Castle-head makes one point, and Mizenhead the other; the latter is the south-west point of the mainland of Ireland, and hence received the name of Notam from Ptolemy. A little within this lies Crookhaven, which in any other country except Ireland, and even in Ireland, in any other of its counties except Cork, would be deemed an admirable port; it is landlocked on every side, with an easy outlet, good anchoring ground, and a depth of three fathoms at low water. From the Mizenhead to Cape Clear, the course is east by north four leagues. This Cape is an island of the same name, and forms the most southern point of Ireland; it is three miles long and one broad. East from this Cape lies the peninsula of Baltimore, which forms one side of a spacious bay, in which there are many inlets and little ports. The coast to the eastward presents Castlehaven harbour, about half a mile across; the channel bold and deep, with a depth of water from thirteen to thirty feet; the harbour of Ross, now nearly filled up with sand; and Court Macsherry, a harbour, which has also suffered from the accumulation of the sand. Corkhead and Poorhead, a steep high promontory, are the two extremities of a bay, in the middle of which is the entrance to Cork harbour; this, which is one of the most capacious and secure in Ireland, opens, from an entrance about a mile in width, to a fine basin, in which are three islands that break the force of the winds and tides, and render it more secure. The sea has evidently encroached on the coast near Youghall, the beach at low water-mark being a bog covered with sea-sand, under which are found the remains of trees. The extent of the sea-coast of the county of Waterford, which from Ardmore Head to Hook Tower, is about 12 leagues, is in fact a spacious bay. The coast is mountainous, presenting to view the highlands of Dunagarvon, Capequin, and Knockandown. On this coast there are no inlets or harbours of moment. Above the bay of Tramore lies, what is called the Strand of Tramore, containing about 2000 acres.

The province of Leinster has 30 leagues of sea Leinster coast, but is deficient in good harbours. Between Wexford and Dublin bay, the coast is lined by dangerous banks, particularly off Athlone. The limits of Dublin Bay are Dalkey island on the south, and the peninsula of Howth on the north, the distance between them being six miles. The south shore rises like an amphitheatre towards the lofty mountains of Wicklow; the north shore is lower and more level. The bay is exposed to the east. To the north of the peninsula of Howth, at the north point of Dublin bay, is the island called Ireland's Eye. The county of East Meath has but four miles of sea-coast, and no port. Drogheda bay, which in fact is the mouth of the Boyne, lies between the counties of East Meath and Louth. The main open bay of Dundalk, may, when it is high water, be regarded as a harbour, but when the tide is out it is absolutely dry. Lough Carlingford is a deep inlet, dividing not only the counties of Louth and Down, but also the provinces of Leinster and Ulster. On both sides of its entrance there are dangerous rocks, but it is well...
IRELAND.

271

sheltered, and has sufficient depth of water for the largest ships.

The province of Ulster comprehends four maritime counties, and has a sea-coast of 100 leagues. Point Cranfield makes the east tide of Carlingford Bay, and from this place to Belachaneir, along the mountainous country of Mourne, there are only a few creeks, capable of receiving nothing larger than fishing boats. The bay of Dundrum lies between that and St. John's Point, which is six miles broad, but shallow, and full of shaws; there is also an inner bay, but this, though convenient and safe, is rendered of little use, on account of the shallowness of the outer bay. The foreland of Point St. John, the Isanium Promontorium of Ptolemy, lies a mile to the south of port St. Anne. The land now stretches to the north-east for five miles, till we reach Killard Point, which is the south-west extremity of Strangford Bay; the other extremity is Quintin Point. Strangford Bay is an inlet, five miles and a half long, and a mile broad; the sea runs through it with great rapidity. This bay opens into the greater Lough Neagh, one of the smallest lakes of Strangford, which runs directly north up to Newtown, and separates a small branch to the west, on which stands Downpatrick. Lough Strangford is a basin, fifteen miles long and five broad; in it are 54 islands. This is the largest salt-water lough in Ireland. From Point St. Quintin to Ballycastle, the land runs north-east, but from the latter to Donaghadee it runs north, with a little inclination to the west, and a very dangerous coast all the way, the shore being lined with great rocks.

Belfast, or the Bay of Carrickfergus, divides the counties of Down and Antrim; it is three leagues wide at its entrance, is easy of access, and well sheltered. Nothernhead forms the south point of the entrance, off which lie the Copeland islands, three in number.

The north coast of Antrim is the most interesting in Ireland, both to the geographer and the geologist: its geology will be considered afterwards, at present we shall merely attend to its geography. Two leagues north from Carrickfergus lies the small port of Oldfield; beyond this there is a bold coast and safe anchorage, to the height of Fairland Point. This promontory, and that of Bengore, constitute the leading features of this whole coast; they stand at the distance of eight miles from each other, both formed on an extensive scale, both abruptly towards the sea. The former lies about seven miles to the west of Ballycastle, and appears, when viewed from sea at a distance, to be an extensive land-head, running out from the coast a considerable length; but, when examined, it is found to be made up of a number of lesser capes and bays, each distinguished by name, the whole forming the headland of Bengore. The most perfect of these capes is called Pleaskin. The mean height of the coast near here is about 1000 feet, while the surface of Lough Neagh, situated in the midst of this part of Ireland, is not elevated more than 30 feet above the ocean. The total height of the cliffs of Cape Pleaskin, from the summit to the base, is 574 feet. Fairhead, the north-east cape of Ireland, the Robogodium Promontorium of Ptolemy, is elevated more than 500 feet above the sea, and forms the eastern extremity of Ballycastle Bay. It presents to view a vast mass of rude columnary stones, many of them exceeding 200 feet in length; and at the base of these gigantic columns, lies a wild waste of natural ruins; of an enormous size, which, in the course of ages, have been tumbled down from their founda-

tion, by storms, or some powerful operations of nature. A savage wildness characterizes this great promontory, at the foot of which the ocean rages with uncommon fury. Scarcely a single mark of vegetation has yet crept over the hard rock, to diversify its colouring; but one uniform greyness clothes the scene all around. The island of Roshberry, or Roglin, six miles from Fairhead, is five miles long, and three-quarters of a mile broad. The phenomenon of the mirage, similar to the faia morgana, is often observed in the strait that separates this island from the main.

Returning to the Bay of Galway, we shall now proceed to the west coast of Ireland. Galway Bay is very capacious, being six leagues wide and seven deep; before it lie the South Arran islands, among which there are no fewer than four passages; these belong to the county of Clare; there are various shaws, sands, and sunken rocks, especially on the north side. When the wind blows from the south and south-west, a heavy swell rolls into the bay of Galway. The coast to the north of this bay is lined with many rocks and small islets, and possesses seven of the principal of which is Buttevy Bay; this has a narrow entrance, but within is four miles long, and two broad, with deep water. Conichin bay is deep at the mouth, but the entrance is difficult and dangerous; the other bays require no particular notice. The west point of Galway is Slieven-head, which is rocky and steep. To the north of this head are many bays, but the coast in general is lined with rocks and shoals. The counties of Galway and Mayo are separated by Killery harbour. The county of Mayo has a long extent of coast, fronting directly towards the north, in which there are many coves and bays. Before Newport Bay, which is four leagues long, with many islands, and has several good roads for the largest vessels, lies Clare Island. The entrance to the bay of Blackvol is four miles long; this bay is formed by the island of Achill on the south, and affords a landlocked harbour. The coast, in this quarter, is studded with islets, of which the most conspicuous are those called the Stags of Broadhaven; after passing these, the coast becomes clear of islets, with steep rocky cliffs. Killala Bay contracts into a harbour which admits small vessels. Sligo Bay is capacious, and has several good harbours and roadsteads. Three leagues west from Ballyshannon, off the coast of Sligo, lies a small island called Ennis Murry, at the south end of which is a large rock above water, with a ledge running for a great distance from it into the sea; so that, to the south-west, the coast is foul as far as Riala point.

The coast of Donegal is mountainous and dreary. Donegal Bay is six leagues wide and seven deep, and contains many harbours. On the north shore of this bay another stretches into the land, called Inver Bay. From the bay of Donegal, the coast is lined with islands, one group of which is called the Roses; the largest of this group is the island of Arranmore, nine miles in circumference, and one mile from the main land. Sheephaven is spacious, but exposed to the north and north-east near it is Horn Head; in this promontory there is a remarkable cavern, with an opening to the land, through which the waves force up a column of water, with a noise that is said to be heard 30 miles. There are some black rocks, called Ensterhull, over against Enishtown, the extremity of which, Caledagh Point, is the north cape of Ireland. To the west-south-west lies Lough Swilly, which is thought to be the Anglia of Ptolemy; it is one of the noblest harbours in Europe,
IRELAND.

being 20 miles long, and nearly two deep, with good anchorage and deep water, so that a large fleet might lie there with ease and safety. As, however, there is scarcely even a village on its shores, it is little frequented, except occasionally by vessels for shelter.

The first object of importance, in tracing the coast of Lounderry, is Loch Foyle, or Foole. Into this loch runs the river Derg, and its tributary streams. Lough Foyle is an immense oval basin, 18 miles long and eight broad. Between Magilions and Green Castle, where it opens into the ocean, it is not above a mile and a half wide, with eight and ten fathoms depth of water. Before this entrance, there is a large sand called the Tunnas, on which the sea sometimes bents with a prodigious noise and violence; the channel between this sand and the main is broad, and at all times 14 or 15 fathoms depth of water. On the east side of the lough there are also shoals, or banks of sand, and some smaller ones on the west; but the two channels between them are wide, and generally four fathoms deep; at the entrance of the river, the water is 10 or 12 fathoms; so that, upon the whole, Lough Foyle is a very safe, capacious, and commodious haven, for the largest fleets.

We shall subjoin to this description of the coasts of Ireland, the following Table of the principal geographical positions on them:

</table>

The effects of such an immense volume of waters as the Atlantic Ocean, acted on, as they often are, by violent westerly winds, upon the west coast of Ireland, in rendering it more angled and indented than any of its other coasts, have already been noticed. But it may be proper also to notice in this place, other effects of the winds on the coasts of Ireland; we allude to the immense accumulation of sand, which they have forced up, by which, in many places, the land, and even villages, have been overwhelmed. The following instances in point, are drawn from a memoir on the climate of Ireland, by the Rev. William Hamilton, published in the 6th volume of the Irish Transactions.

"The effects of the winds," he observes, "are particularly distinguishable in the northern province of Ulster; but they are by no means confined to this coast, being strikingly observable, even on the east coast. At the entrance of the river Bannow, in the celebrated barony of Forth, in the county of Wexford, vestiges of runs, traced with difficulty amid the heaps of barren sands, serve to ascertain the site of a town," which derived its name from the river on which it stood. The town of Bannow had the privilege of sending representatives to Parliament; and so late as the year 1626, it is registered in the custom-house books of Wexford as having four streets which paid quitrent to the crown. The only remains visible in 1786 were the walls of the church; there is not, on or near the site of the town, but one poor solitary hut. Amid the sands between Portrush and Dunluce in the county of Antrim, in the year 1783, the ruins of a village might be seen deserted by its inhabitants. In the year 1787, the peninsula of Hornhead, in the county of Donegal, contained vestiges of enclosures, so small and so numerous as to mark the residence of a considerable number of families; but then it was quite a desert. Rather more than a century ago, the peninsula of Rossull, which lies between the harbours of Sheepaven and Mulroy in the county of Donegal, was selected as the residence of one of the noble families of Hamilton; at present the gardens are totally stript of trees and shrubbery by the fury of the western winds; the limits of the courts, the flights of steps, and the terraces, can scarcely be traced amidst the heaps of sand which overwhelm them. The mansion itself was, when described by Dr. Hamilton, fast approaching to destruction, the lower apartments being already filled with sand, which was beginning to rise above the thresholds; it is said that 1200 acres of land were also buried, in a short time, in irrecoverable ruin. Dr. Hamilton mentions two other striking instances of the encroachment of the sand on the coast of Donegal; one of a house, which had not been long built when he saw it, the roof of which was just emerging from the sand; the owner told him that the house had at first a considerable tract of pasture ground between it and the sea shore, but that latterly he was obliged every year to dig it out of the encroaching sands. Thirty or forty years before Dr. Hamilton wrote, there was a forge in a village of Favet on the northern coast of Donegal, but then there were no vestiges of it, except some stones in the midst of loose and shifting sands.

Dr. Hamilton is of opinion, that the Atlantic storms on the west coast of Ireland are of more frequent occurrence, and superior potency, to what they formerly were. "Every person on our coasts," (he observes) "whose situation has made the construction or preservation of embankments against the influxes of the ocean necessary, knows, by painful experience, how much his labours have of late years increased, and how impotent works, formerly effectual, are now found to be in repelling the increasing tides of the great ocean; public roads encroached on, walls beaten down, streams less passable than heretofore, meadow and tillage land overtopped and more deeply inundated; all concur to prove encrescing tides and frequency of storms on our coast."

A short description of the Nymph bank seems properly to belong to the hydrography of Ireland, and may therefore be inserted in this place. It lies in St. George's Channel, about 10 leagues off the coast of Waterford in Munster. Its distance from the high land of Dungarvon is about 11 leagues S.E. The appellation Nymph Bank strictly applies to that part of this sand bank which lies opposite Waterford; the extreme point of it is nearly 20 leagues from the land; the
Statistics

depths on it are from 45 to 70 fathoms; the ground consists chiefly of pebbles and broken shells. It is a
great fishing bank, and abunds in cod, hake, ling, 

herring, skate, whiting, red gurnet, &c. The sand 
banks, or grounds, as they are called, between Dublin 

and Wexford, have been already shortly adverted to.
They are very extensive, but not wining as grounds of 

this description usually are, but running in a straight 

line N.N.E. and S.S.W., being far short from the land 

with their north end; as they go to the south, they 

come nearer the land. Near the Tusker rock, two 

leagues E.N.E. from Carseore point, where they terminate, 

they are not more than 2 miles distant from the land; whereas the distance between the north end, 

near the isleland of Dalkey, at the entrance of Dublin 

bay, and the land, is above eight miles. They are all 
of stony ground, in some places but one fathom deep; 

but, at the north end, two fathoms and a half, or three 
fathoms; the channel between these grounds and the 

land is deep all over. The ground of the Irish Sea, 
generally speaking, as well in the middle as under the 

land, is almost everywhere clear sand; in some places 

black and muddy earth; in very few places, rough and 

sharp; and scarcely anywhere, but in the bay of Wick- 

tlow, so hard that the anchors cannot take hold of it. On 

the west side of Ireland the tide flows against the land, 

and the ebb falls back from it into the sea; the flood 
tide going from, and the ebb towards the west. Hence 

the tides on this coast are often very strong and high, 

not only on the open shores, but in the bays and inlets. 

On the other side of Ireland the tide ebbs and 

flows along the land. On the north side, the tides run 
in the same direction as on the west side; that is, the 

flood from the west, and the ebb towards it. But upon 

the east side, from Fairhead to Carlingford, the flood 

comes from, and the ebb falls to the north; from 

Carlingford to Carseore it flows from the south, and ebbs 

from the north. For though, on all this side, the flood 

runs along the land, yet not beginning from the same, 

but from opposite points, the two floods coming, the 

one out of the main sea in the north, and the other out 
of the main sea in the south, the two meet and stop 

each other before Carlingford haven. From the Tusker 

rock and Carseore as far as to Cape Clear, being the 
whole south-east coast of the province of Munster, the 

flood falls along the coast E. N. E. and the ebb W. S. W. 

but upon the rest of the coast of Munster beyond Cape 

Clear to the westward, which coast lies west and by 

south, the flood flows eastward, and the ebb falls to the 

west. In the entrance to the channel or haven of 

Wexford, the tide ebbs and flows three hours sooner 
than without in the open sea; so that when it is high 

water in the entrance to the haven and upon the bar of 

Wexford, the flood is still running by it to the north 

for the space of three hours; the effect of which is, 

that the end of the great sand which lies just before the 

haven of Wexford is cast up more and more to the north, 

and the channel on the north side of that sand, which 

is the entrance of the haven, is more open to the north 
than it was formerly.

CHAP. II.

Soil of Ireland—Boor—Forests—Climate—Botany—

Geology—Mineralogy—Mineral Waters.

Soil of Ireland—It is extremely difficult to give a clear, definite, and 

accurate idea of the nature and properties of the soil, 
even of a farm consisting of a few hundred acres; for, 
in the first place, very different ideas are affixed by dif-

ferent people to the terms by which the various kinds 
of soils are designated. The farmer in Norfolk, for in-

stance, when describing what he deems a clay soil, has 
reference to a very different kind of soil from that which 
the Suffolk farmer means by the same term; the lat-

er, accustomed to soils of the most tenacious and stub-
born clay, would deem the soil to which the Norfolk 
farmer gives that appellation only a loam, or, at most, 
a clayey loam. But, in the second place, in most tracts 
of land, even of a few thousand acres, there are not 
only a great variety of soils, but the passage from one 
kind of soil to another is often so sudden and extreme, 
that no one appellation will properly designate the soil 
even of a single field.

The first of these difficulties applies, but only in a 
slight degree, to any attempt to describe the soil of Ire-

land; the second scarcely applies at all; for if there be 
one circumstance by which the soil of this country is dis-
tinguished from the soil of most other countries, and 
especially from the soil of England or Scotland, with 
which we should most naturally compare it, it is, that 
the soil of Ireland is nearly uniform throughout the 
whole of that kingdom. We do not by this mean, that 
there are not varieties of the particular genus of soil, 
which does prevail in Ireland; but that, with very few 
exceptions, there is only one genus of soil over the 
whole country. In order, therefore, to give as accurate 
and clear account of the soil of Ireland as we can, in a 
few words, we shall, in the first place, describe it neg-
atively, and then point out the soils that actually prev-
ail in it.

There is no clay soil in Ireland; by that term we 
mean such clays as are found in Oxfordshire, in some 
parts of Essex, throughout high Suffolk, in some parts 
of Surry, &c.; or, in other words, soils of uncommon 
strength, stubbornness, tenacity, and retentiveness. Ge-

erally speaking, there is no sandy soil, such as is met 
with in Low Suffolk, near Godalming, in Surry, &c. 

and there is no chalky soils, such as abound in Surry, 
Sussex, Hampshire, Wiltshire, &c. Gravelly soils, either 
such as prevail in some parts of Middlesex, consisting of 
yellow gravel, evidently tinged with the oxide of iron, 
or such as consist of uncoloured gravel, and are, in 
Scotland, called sharp soils, are seldom or never met 
with in Ireland.

Having thus pointed out the kind of soil which are 
not at all, or scarcely found in Ireland, we shall next 
describe the kind of soil that prevails over the country. 
It may be aptly described as a loam; this is the genus, 
but there are many varieties. Though there is no clay 
soil in Ireland, there is in some places, especially in the 
county of Tyrone, clayey loam so strong as to make 
good bricks. The loams, however, most prevalent over 
the whole island, are of a lighter nature; they are fer-
tile, not merely on account of their component parts, 
but also because they, for the most part, rest on a calca-

culous basis, and are, in fact, mixed up with limestone 
rubble. One of the most striking features is the shal-

lowness of the soil of Ireland; in many places the rocks 
appearing on the surface, or at no great depth, even in 
the most flat and fertile parts, as Limeric, Tipperary, 
and Meath. Such is the nature of the soil of Ireland, 
generally speaking, a fertile loam, with a rocky sub-
stratum.

The extent of this rich soil is not very considerable 

in the hilly part of Ireland; though, even amidst the 
rocky and dreary mountains of Donegal, the soil of the
There is also another division of the bogs of Ireland into three sorts—mountain bogs, red bogs, and floating bogs. With respect to the last, which is the most singular kind, it has been ascertained that, a quantity of water lies in a body between the turbarry and the gravel, which keeps the turbarry in a buoyant state, and contributes to the growth of the fungus substance. When the turf-cutter cautiously approaches the bottom of a turf-hole, the water frequently bursts up through a close covering of two or three feet, and exposes him to imminent danger.

In September 1809, a warrant was issued, by which commissioners were appointed to inquire into the nature and extent of the several bogs in Ireland, and the practicability of draining and cultivating them. These commissioners laid before Parliament four reports on this important subject, from which the following particulars have been collected. The limits of this article necessarily compel us to draw from them only the most relevant and interesting information; and we must refer such of our readers as wish for further particulars, especially on the substances found in these bogs, the analysis of these substances, and the most eligible means of draining and cultivating the bogs, to the reports themselves.

In the first report, the commissioners state, that they consider the greater part of these bogs as forming one connected whole; and that a portion of Ireland, of little more than one-fourth of its entire superficial extent, and included between a line drawn from Wicklow-head to Galway, and another drawn from Howth-head to Sligo, comprises within it about six-sevenths of the bogs drained of mere mountain bogs, and bogs of less extent than 600 acres. This portion, in its form, resembles a broad belt, drawn across the centre of Ireland, with its narrowest end nearest the capital, and gradually extending in breadth as it approaches the Western Ocean. This great division of the island, extending from east to west, is traversed by the Shannon from north to south, and is thus divided into two parts. That portion of the bogs which lies to the westward of this river, contains more than double the extent that are to be found to the eastward. The commissioners are of opinion, that if the bogs of Ireland (exclusive of mere mountain bogs, and bogs under 500 acres) be supposed divided into 20 parts) about 17 of them will lie in the great division just described, viz. 12 to the westward, and 5 to the eastward, of the Shannon; and, of the remaining three parts, two will lie to the south, and one to the north, of this division. Most of the bogs which lie to the eastward of the Shannon, occupying a considerable portion of King's County and the county of Kildare, are generally known by the name of the Bog of Allan; but this is not one great morass. On the contrary, the bogs to which this appellation is applied are perfectly distinct from one another, often intersected by ridges of dry country, and inclining towards different rivers. In general, there is no spot of these bogs, to the eastward of the Shannon, so much as two Irish miles distant from the upland and cultivated districts.

The result of the investigations, set on foot by the commissioners, with regard to the extent of the bogs in Ireland, is given in their fourth report, laid before Parliament in the session of 1813—14, as follows:—

**Different kinds of bogs.**

1. Wallow bogs, or shallow lakes, overspread with little tufts or islets, consisting of reeds, rushes, coarse grass, and sometimes small shrubs. As the roots of these are closely interwoven, and sometimes rest on ground rising to the surface of the bog, these bogs may be passed over. Most of them are found in Queen's and King's Counties. 4. The peat moors.

**Total**: 1,013,353

Besides, there are the three mountain districts of Wicklow, Erris, and Connemera, which contain, respectively, 97,000, 170,090, and 120,000 acres; and in the two last districts, there are of mountain peat soil, respectively, 135,500 and 200,000 acres. The extent in Wicklow has not been ascertained. The mountain peat soil in other parts of Ireland is supposed to amount to about 900,000 acres. Of the bogs under 500 acres, there are about 90 in the county of Cavan alone, containing 17,000 acres in all; and the commissioners suppose, that the other parts of Ireland cannot contain less than ten times as great an extent of these lesser bogs as the single county of Cavan.

"From all the above data (the commissioners observe) we can confidently pronounce, that the extent of peat soil in Ireland exceeds 2,830,000 English acres, of which we have shewn at least 1,875,000 to consist of flat red bog. The remaining 1,255,000 acres form the covering of mountains."

The strata of which the bogs in Ireland are generally consist, or which lie below them, will more properly be considered when we come to treat of the geology of Ireland. At present we shall extract from the reports of the commissioners the heights of some of the bogs.

In that which is generally called the Bog of Allan, the highest summit of Lallymure bog is 236 feet above high water mark in Dublin Bay, the lowest point 214 feet; the highest point of Timahoe bog 229, the lowest point 222; the highest summit of the Bog of Mounds 296, the lowest point 224; and the highest point of Clane bog 298, and the lowest point 255 feet above high water mark in Dublin Bay. The greatest height of the bogs on the west of the Shannon, above Lough Ree, is 76 feet, the lowest point 29 feet; the greatest depth 49 feet, the least depth 11 feet. The greatest height of the bogs on the east of this river, in the counties of Longford and Leitrim is 114 feet, the lowest point 30 feet; the greatest depth 43 feet, and the least 30 feet. The greatest height of the surface of the bogs in the district of the Boyne and above the sea at high water mark in Dublin Bay, is 236 feet, the least height 218; the greatest depth 40, the average depth 22 to 25 feet. The greatest height of the surface of the bogs to the northward of the Brusna is 274 feet, the least height 114; the greatest depth 45, the average depth 30. The greatest height of those to the southward of this river is 310 feet, the least height 111; the greatest depth 45, the average 22 to 25. The greatest height of the bogs in the district of the Inny and Lough Ree is 233 feet, the least 176; the greatest depth 47 feet, the average 30 to 37 feet.

As it is obviously a matter of the highest national importance, that these bogs, if possible, should be reclaimed, and rendered capable of conducting to the surface of man, the commissioners particularly directed their attention and investigations to ascertain how far, and by what means, this was practicable. They remark, that "peat moss ought to be considered as partaking, in its general nature, of the property of sponge completely saturated with water, and giving rise to different streams and rivers for the discharge of the surplus waters which it receives from rain or snow." In the district of Allan, as well as in many other districts, these streams have worn their channels through the substance of the bog down to the clay or limestone gravel underneath, dividing the bog into distinct masses, and presenting in themselves the most proper situations for the main drains; and which, with the assistance of art, may be rendered effectual for that purpose.

Another circumstance is favourable to this great undertaking. Their surfaces, in general, are by no means level, but with planes of inclination amply sufficient for their drainage. The highest summit of any part of the bogs in the eastern district of Allan is 298 feet above the level of the sea, taken at an ordinary spring tide in the Bay of Dublin; and the lowest point is 214 feet above the same level. In the Bog of Timahoe, a part of its water is discharged into the sea at Drogheda, and another part below Waterford.

We have thus stated the two grand facts on which the commissioners rested the practicability, and indeed the facility, of effecting the drainage of the bogs of Ireland, and on which they accordingly formed their plans. That they will be successful, there can be little doubt, provided they are executed with skill, and sufficient funds are allowed. And, as far as the estimates of the engineers may be depended upon, the expense will be amply counterbalanced by the quantity of useful land recovered. The estimate for draining the eastern district of the Bog of Allan is £147,052, 6s. 11d., and the quantity of land which would be gained is 36,430 English acres, or about £10 an acre.

Ireland, like all other countries formerly, abounded in forests. According to Boase, on the authority of Gervais Cambrensis, who came into Ireland on its first con...
IRELAND.

Statistics.

quest, in company with Henry II., this country was full of woods on every side; but the English, on gaining possession of it, cut them down, partly in order to deprive the banditti of their lurking places, and partly to gain the greater scope of profitable lands. Another cause operated, which operates in all countries—the desire to obtain wood for fuel. Forests, however, were still numerous in those parts, especially, over which the English had not acquired a perfect and tranquil power; but after the quelling of the great rebellion in the time of Elizabeth, the forests were still more reduced in extent and number. The same motives which operated with the conquerors on their first invasion, operated now. Besides, the prospect of gain for the sale of the timber was a further inducement. Immense ship loads were sent to foreign parts; and whereas, before this period, there was not a single charcoal manufactory, on the subduing of the rebellion, a great number on a very extensive scale were erected.

All these causes, however, though operating probably with a progressive effect, had not denuded Ireland entirely of forests in the middle of the 17th century, the period when Boate published his Natural History of that country. He complains, indeed, that great part of Ireland was very bare of woods in his time; and that, in some places, you may travel whole days long without seeing any wood or trees, except a few about gentlemen's houses; and, particularly, instances the route from Dublin, as far as Dromore, by Dundalk and Newry, being above 60 miles, in some parts whereof you shall not see so much as one tree in many miles; and adds that the "great woods, which the maps do represent to us upon the mountains between Dundalk and Newry, are quite vanished." Notwithstanding these complaints, there is not a word of the time of the author, large tracts which no longer exist. In Leinster he states, that the counties of Wicklow, and King and Queen's Counties, were throughout full of woods, some many miles long and broad; and that part of the counties of Wexford and Carlow were greatly furnished with them. In Ulster, there were, in his time, great forests in the county of Donegal, and in the north part of Tyrone; likewise in Fermanagh, along Lake Erne, in Antrim, and in the north part of Down. The greatest part of the latter county, however, as well as Armagh, Monaghan, and Cavan, which, in the war with Tyrone, were encumbered with great and thick forests, were, in the time of Dr. Boate, almost everywhere bare. With respect to Munster, he represents the counties of Kerry and Tipperary as possessing sundry great forests, notwithstanding the English, especially the Earl of Cork, had made great havoc with the woods. In Connaught he states, that there were very few forests, except in the counties of Mayo and Sligo.

At present, such was the state of Ireland with regard to forests, during the middle of the 17th century; but it is much changed at present, for in Donegal and some other of the counties represented, by Boate, as possessing extensive forests in his time, there are now none. Wood is more general in the county of Fermanagh than in any other county of Ireland. Oak abounds throughout the glens of Wicklow, and upon the mountains of Kilkenny, but it is of considerable size; and in other parts of the country is by no means common. Ash is confined principally to Fermanagh, and in some parts of Tyrone and Cavan. As proofs of the denuded state of parts of Ireland with respect to wood, it may be mentioned, that in the county of Clare, there are only 780 acres of wood, or rather of plantation; and that in Kilkenny, there are only 1800 acres.

The fertility of every country depends mainly upon its soil and climate. The soil of Ireland, we have seen to be, in general, of a very fertile quality, but at the same time, in most places very shallow, and resting upon a rocky substratum. Such a soil, in a dry climate, could not be very productive; but, fortunately for Ireland, her climate is most admirably adapted to her soil. The situation of this country, which, on all sides except the eastern, lies quite open to the Atlantic, in connection with the circumference, that westerly, and especially south-westerly winds, prevail more in this country, even than on the opposite coast of England, renders its atmosphere extremely cloudy and moist. These winds, generally speaking, may be said to blow three-fourths of the year; and as they blow often with considerable violence, this cloud, it does not the dryness of the soil, prevent the excessive moisture of the climate from being unhealthy. The same causes which render the climate of Ireland more moist than that of Britain, and the winds from the west and south-west more prevalent, render also the climate more uncertain, and the seasons more irregular; generally speaking, however, showers are very frequent, especially in the winter season. In this season, also, the south-west and south winds prevail more than in the other seasons of the year; in summer and autumn, the west prevail; in spring, the east, south-east, north-east, and north. Storms are more frequent in autumn and winter, than in spring and summer; the months most liable to them are November, December, January, and February.

The temperature of Ireland is milder, and through-out the year averages a higher degree than the temperature of England; but this must be understood as applying not so much to the higher heat of the summer, as to the more cold of the winter and spring. In the south and south-west of Ireland, it is said to happen that winter covers the low ground with snow, or locks it up in frost, for any length of time; and even in the middle of the country, snow of a month's duration on the plains is very uncommon. Rain, however, in winter, through all Ireland, is abundant; and the moisture this occasions, gives a feeling of coldness, which, if not compared with the thermometer, would lead to the supposition, that the temperature of the air was really very low. The winter continues commonly in the north and central parts seven or eight months, fires in chambers being requisite from about the middle of September to the middle of May. The seasons are later than in England: "the spring and autumn more tardy in their approach, as also the winter; the fall of the leaf being later than in England." The differences of temperature between the north and south of Ireland, seem to arise more from the different elevation of the land, than from difference of latitude. Indeed, the cause of the different effect, the extent of Ireland, in a meridian line, not being above four degrees of latitude. The situation of the country with respect to the ocean, also affects its temperature. The western and southern parts are more moist and temperate than the eastern and north-eastern, and the coasts, than the interior. It has been also remarked, that, where the substratum is limestone, the snow dissolves sooner than elsewhere.

Such is a general description of the climate of Ireland; but it may be proper to select some particular facts, to confirm and illustrate the truth and accuracy of this description.

And, first, with respect to temperature. Generally speaking, the mean temperature of the north of Ireland is about 48°; of the middle 50°; and of the south 52°, State of the

At Kilkenny, the thermometer during winter seldom sinks below the freezing point; and during the summer it seldom rises above 79° in the shade. It has been observed as high as 84°. The average heat of summer is between 70° and 73°. At Limerick, the greatest height of thermometer in the shade is 72°; the greatest depression 55°. In winter, it is under 55°, but never below 25°.

According to Dr. Rutty, the range of the thermometer in Dublin is about 36°. The medium atmospheric heat of five years, viz. 1794, 1796, 1797, 1799, and 1800, was 50.15 plus; the maximum is 51.50; and the minimum was 14.50.

Limerick. From observations made at Limerick, it appears that, for the space of ten years preceding 1811, the barometer was never observed higher than 30.5, nor lower than 28.5, except in two instances when it stood at 28. The greatest height to which the barometer rose, in the course of thirteen years, at Cork, was 30.4 inches, and that only once; its lowest height was 28.2.

Dr. Smith, in his History of Cork, remarks, that it appears from a regular diary of the weather, kept for several years in that city, that the winds blow from the south to the north-west three-quarters of the year at least.

From a register kept at the Botanic Garden, from 1802 to 1811, it appears that the following is the order of the months, according to their dryness. June, February, April, March, May, October, January, September, August, November, July, December. In all the months of June, during the above period, there fell only 12,070 inches, and in February only 12,392; whereas in December there fell 27,310, and in July, 24,146.

From the following Table it will appear, that the order of the months, taken according to their dryness, varies considerably from this at Belfast.

</table>

The materials for the natural history of Ireland are by no means rich or abundant. Consequently, as they cannot be systematized, and as our limits, as well as the nature and object of this article, compel us to be brief and general, we shall merely give some notices on the three great branches of botany, zoology, and mineralogy.

The study of botany, (observes Mr. Aikin,) has been less cultivated here than in any other part of the united empire; and the neighbourhood of Dublin, which has been the best explored, affords no rare and few characteristic plants. From the general mildness of the climate, the extensive tracts of bog, and the vast mountainous ranges that intersect the country, and afford copacious basins for its numerous lakes, it is obvious that the flora of Ireland, when complete, will probably contain several species that are strangers to the rest of the British islands. On the mountains of Sligo is found the Saxifraga umbrosa. known in our gardens by the name of London pride; and the romantic scenery of Killarney, in the county of Kerry, is the most northern habitat of the Arbutus Unedo. The heaths abound with the stately Erica Dubéci; and the mountain aven, bear-berry, with other alpine plants, expand their neglected blossoms, and trail their glowing festoons of clustered berries, unnoticed amidst the wild solitude of their rocky fastnesses.

The zoology of Ireland is very similar to that of England. It is said that magpies and foxes were unknown here, till introduced by the English, toward the beginning of the 18th century. Moles, toads, and all kinds of serpents, are still unknown. The Irish grey-hound, or wolf-dog, formerly of great use in clearing the country of wolves, is now seldom met with, the breed being nearly extinct. Its appearance is at once beautiful and majestic; its height about three feet; its colour generally a white or cinnamon; its aspect mild; its disposition gentle and peaceable; but its courage and strength so great, that, in combat, the mastiff or bull-dog is far from being equal to it. The breed of the wolf was not extinguished in Ireland till the beginning of the 18th century. Herds of deer were formerly very numerous; but the progress of cultivation has rendered them rare. A species, at present entirely extinct, existed in ancient times, as enormous horns are dug up in various parts of the kingdom. "Some of these horns have been found of the extent of fourteen feet from tip to tip, furnished with brow antlers, and weighing three hundred pounds. The whole skeleton is frequently found with them. It is supposed, that the animal must have been about twelve feet high." The cattle, horse, sheep, &c. of Ireland, will be noticed under the head of agriculture; and the salmon and other fish, which are made an object of important traffic, under the head of fisheries. But, to this short notice of the zoology of Ireland, we shall here add a few words regarding some rather rare species of fish, which are found in its lakes.

Lough Neagh contains a great variety of fish. Besides salmon, a large kind of trout, bream, and perch, it contains the pollan, which is the same as the ferra of the lake of Geneva, and the grunia of Bal Lake in North Wales. Lough Erin, a small water in the county of Down, is remarkable for producing pike, trout, and eels, of an enormous size. Pikes of 26 lb. weight, and yellow trouts, little inferior in flavour to the char, of 12 lb. weight. The char is said to be found in the loughs in the mountainous part of the county of Waterford. The oysters taken near Carlingford, are celebrated for the peculiar richness and delicacy of their flavour.

Ireland is said to rest on a bed of granite; and this Geology and Mineralogy, is highly probable, since granite is very conspicuous and abundant on its highest mountains. Of it the central mountains in the county of Wicklow are formed, and likewise that ridge which separates the counties of Wexford and Carlow. That portion of the county of Kilkenny, which lies between the Nore and the Barrow, abounds in granite of various shades, grey, red, and yellow; there is a valuable quarry of it at Mount Lofus. In some parts of the county of Down, it is met with in detached masses; and in other parts it appears to compose the hills; it also abounds in the neighbourhood of Dublin; and is found emerging from
IRELAND.

beneath the basalt mountain of Sleeve-Gallen in the county of Derry. It is every where used for architectural purposes.

The following facts respecting the granite near Dublin, may be interesting in a geological point of view. From the shore, on the south side of Dublin Bay, there passes, in a south-western direction, a broad body of granite, bounded on its eastern and western sides by incipient rocks of great variety. At Killarney, schistose rocks repose for a considerable extent on granite; and the line of junction, which begins at the sea side, may be traced for some miles across the country. On the shore, it is traversed by numerous veins, many of which are themselves composed of granite; and, in some instances, two veins of this substance, differing from each other, and from the mass, in fineness, and in the proportion of their ingredients, are seen to intersect. The actual contact of granite with incipient rocks, has been observed at several places in the counties of Dublin and Wicklow. On the shore of Dublin Bay, not far from Blackrock, a mass of compact limestone is visible within a few fathoms of the granite; but, in the intermediate space, the rock is concealed. On the western boundary of the granite rocks nearest to Dublin, rocks composed of trap occur; and thence, to the south-west, along the borders of the counties of Wicklow and Kildare, there are various intermediate rocks between the granite and the limestone of the flat country to the westward.

Limestone.

Limestone is met with in great abundance in all the counties of Ireland, except Wexford, Wicklow, Tyrone, and Antrim. It has already been mentioned, in treating of the soils of Ireland, that the rivers Barrow, Lee, Bride, Kenmare, and Blackwater, form the boundary of the limestone districts in their respective courses. Of this mineral, there are several kinds, both such as are interesting to the geologist, and such as are useful in an economical point of view. The quarries in the immediate vicinity of Dublin, afford many varieties of calcareous productions. The celp of Mr. Kirwan is the prevailing rock. Brown spar is found in some quarries; and beds of magnesian limestone have been observed on the Dodder. The limestones of Ireland are not less important in an economical point of view. Limestone of a fine white grain, lying in strata from four inches to two feet thick, and of which columns have been raised between nine and ten feet long, and from fifteen to eighteen inches in diameter, abounds at ArdBrecan, in Meath. This limestone receives a very high polish; and, when long exposed to the air, assumes a greyish colour. Blue and white limestone found in the county of Derry. Some of the former is little inferior to marble. But perhaps the most that the full limestone for building is found in Kilkenny. It is of various colours, white, redish, and black. The last is of a remarkably fine texture, and susceptible of a high polish. All the limestone of Kilkenny contains marine shells of various species, as well as impressions of corals, &c. Marble, by no means of inferior quality, is met with in many parts of Ireland. The most beautiful is that of Kilkenny, the Black Quarry, which lies about half a mile to the south of the town of Kilkenny, affords a species of marble nearly equal in quality to that of Italy. The ground is black, varied with white marks, which assume a stronger tint when exposed to the air. About 50 tons annually are exported. Marble is also found in the counties of Cork, Armagh, Down, Kerry, &c. Limestone, containing iron and manganese, is found in various parts of Kilkenny. A species of whetstone, which, after being boiled in oil, is used by the country people for whetting razors, &c. is met with on the mountain of Mangerton. The mountain of Altahaney, in county Down, abounds in white calcareous spar, which is used for tombstones, window-stools, &c. In the Cave of Dunmore, in the county of Kilkenny, alabaster abounds in large masses.

Basalt next claims our attention, in this necessarily Basalt imperfect account of the mineralogy of Ireland. The basaltic district of this country, occupies a range of coast stretched out from the estuary of Carrickfergus on the one hand, to Lough Foyle on the other, and extends inland to the southern limits of Lough Neagh.

The basaltes of this district is generally amorphous, but not unfrequently disposed in thick beds. At the Giant's Causeway, it is most perfect in its form. Here, there are large pillars of it perpendicular to the horizon; in other places, their position is oblique; and in a few, the basaltic pillars form a variety of regular curves. At the Doon Point, in the island of Raggally, all the three kinds are seen, the pillars being perpendicular, horizontal, and bending. (See Giant's Causeway.) The promontories of Fairhead, and Bengore, (see Fairhead,) and Cape Pleskin, have already been mentioned, in describing the coast of Ireland; but it will be proper in this place, again to advert to the last in a geological point of view. About ten or twelve feet from the soil Cape Pleskin begins to assume a columnar tendency, forming a range of massy pillars of basaltes, which stand perpendicular to the horizon, presenting, in the sharp face of the promontory, the appearance of a magnificent gallery or colonnade upwards of sixty feet in height. This colonnade is supported on a solid base of coarse black irregular rock, near sixty feet thick, abounding in blebs and air-holes; but though comparatively irregular, it may be evidently observed to affect a peculiar fissure, tending, in many places, to run into regular forms, resembling the shooting of salts, and many other substances, during a hasty crystallization. Under this great bed of stone, stands a second range of pillars between forty and fifty feet in height, less gross, and more sharply defined than those of the upper story; many of them, of a close vein, emulating even the neatness of the columns in the Giant's Causeway. This lower range is borne on a layer of red ochre stone.

The ranges of pillars are more perfect in proportion as they lie deeper in the ground. The second range of Cape Pleskin, consists of pillars more perfect than the upper range, and the basalt itself has fewer irregularities and imperfections; and the pillars of the Giant's Causeway, which lie still lower, are yet more perfect, as well as the basalt more close and uniform in its texture. Where the forms of crystallization are on a solid base imperfect, the pillars assume various directions; but their general and natural position appears to be horizontal.

The following is a list of the strata at Cape Pleskin, Strata as given by Mr. Hamilton on his Letters on this coast, here.

No. 1. Summit, irregular basaltes, shivered and cracked at the surface, . . . . . 12 feet.
2. Perpendicular range of gross pillars, containing air-holes, . . . . . . . 60 feet.
3. Gross bed of rude basaltes, shewing marks of a tendency towards forms, resembling an imperfect crystallization, . . . . . . . 60 feet.
4. Second range of regular pillars, neat, and divided into joints, . . . . . . . . . . 40 feet.

Carry over . . . . 172 feet.
The reports of the commissioners for examining and draining the bogs of Ireland, (to which we have already been indebted,) enable us to add to the sketch just given, of the geology and mineralogy of some parts of this country, a few particulars on these subjects. At the northern edge of the island of Allan, which adjoins the bog of that name, stratified limestone makes its appearance at the surface, at an angle of 5°, and with a dip 20° east of south. Between this edge and the base of the Hill of Allan, hills of limestone occur; but at the base, a rock appears composed of breccia; thin beds of a deep brick red slate; clay much intermixed with mica, is found interstratified with the breccia. To the south rises the Hill of Allan, composed of an irregular unstratified mass of fine grained greenstone, the crystals of hornblende and feldspar being very minute. Near the summit, the rock becomes more crystalline. Detached masses of beautiful porphyritic greenstone, thickly studded with large crystals of feldspar, are frequently met on the surface. A hill to the south-west of the Hill of Allan, is also composed of greenstone.

The information regarding the strata of part of the Bog of Allan, (and it is highly probable, that the other bogs of Ireland are similarly constituted,) which is contained in the first report of the commissioners, we shall give in the words of that report.

"It appears from Mr. Griffith, (the gentleman employed to survey this district,) that each of the four bogs included in the subject of his report, is a mass of the peculiar substance called peat, of the average thickness of 25 feet, nowhere less than 12, nor found to exceed 42; this substance varying materially in its appearance and properties, in proportion to the depth at which it lies. On the upper surface, covered with moss of various species, and to the depth of about 10 feet, composed of a mass of the fibres of similar vegetable substances in different stages of decomposition, proportioned to their depth from the surface,—generally, however, too open in their texture, to be applied to the purposes of fuel. Below this, lies generally a light blackish brown turf, containing the fibres of a moss still visible, though not perfect, and extending to a further depth of perhaps 10 feet under this. In the instance exhibited in the section at the close of Mr. Griffith's report, are found small branches and twigs of alder and birch; but we do not understand him as being of opinion, that such is by any means generally the case. At a greater depth, the fibres of vegetable matter cease to be visible; the colour of the turf becomes blacker, and its substance much more compact; it is fuel more valuable, and gradually increasing in the degree of blackness and compactness proportionate to its depth. Near the bottom of the bog it forms a black mass, which, when dry, has a strong resemblance to pitch, or bituminous coal, and having a conchoidal fracture in every direction, with a black shining lustre, and susceptible of receiving a considerable polish. Immediately below this lower stratum, there is generally a mottled stratum of yellow or blue clay, varying in thickness from one to six feet. In some places, the peat rests on a thinner stratum of yellowish white marl, containing on an average about 60 per cent. of calcareous matter. This stratum of clay in this district, universally rests on a solid mass of clay and limestone gravel mixed together, and extending to an unknown depth."
Statistics.

IRELAND.

In the peninsula of Howth, grey ore of manganese has been obtained in considerable quantity. It is also found in various parts of Killkenny, in the mountains of Glanmore, in Mayo, and in several other counties. Cobalt is found in the copper mine at Mucross; and a variety of the earth black cobalt ore of Werner, has been found in the peninsula of Howth. Fragments of tin-ore occur in the gold mine in Wicklow. Porcelain earth, in purity equal to the “China clay” of Cornwall, has been found on the southwestern side of the same county.

Coal.

Coal is met with in various parts of Ireland. In Ulster there are two coal mines worked; one in Antrim, at Ballycastle, and the other in Tyrone, near Dunganon. In Connaught, collieries are worked near Arigna, in the county of Leitrim. The province of Leinster, however, seems to possess the most abundant supplies of coal, which is worked near Castle Coomer, at Doomano, in Queen’s county, and at Kilkenny. Castle Coomer colliery is the largest in the kingdom. Forty thousand tons are raised annually. The number of colliers employed is 600. The coal is extracted at the expense of 10s. per ton. This coal is generally deemed one of the most pure found anywhere. Mr. Wakefield, however, represents it, as well as all the other coal of Ireland, as of an inferior quality to the bituminous coal of England. In the province of Munster, a vein, the continuation of the Castle Coomer coal, is wrought in Tipperary. The barony of Duhallow, in the county of Cork, is the only part of the southern portion of the province of Munster in which coal has been discovered. This vein extends to Kerry.

Mineral waters.

Mineral springs are found in almost every county. They are chiefly chalybeates. Those most frequently visited by invalids are Lucan, near Dublin; Swadlendar, in the county of Cavan; Johnstown, near Ullingford, in the county of Kilkenny; and Mallow, in the county of Cork.

CHAP. III.

Landed Property—Tenures—Estates—Farms—Leases

—General Character of the Agriculture of Ireland—

Arable Husbandry— Implements— Crops— Wheat, &c.

Tenures.

The tenures by which almost all the estates in Ireland are held, are derived from grants made in the times of Henry VII. Queen Elizabeth, Cromwell, or William III. A few proprietors, however, especially in the province of Connaught, hold their estates by original title to the soil.

In the History of Ireland, we have already adverted to the forfeitures of landed property, which arose out of the frequent resistance which the Irish made to the power of the English. In this place, it may be proper to consider them more particularly, as we shall thus more clearly point out the titles on which by far the greater part of the landed property of Ireland is held. By the attainder of John O’Neil, and his associates, in the reign of Queen Elizabeth, more than half of the province of Ulster was vested in the crown, which was bestowed upon the English lords, in such a manner as to secure the English power in Ireland. After the rebellion of the Earl of Desmond was quelled, his immense estate was forfeited, and appropriated to the same pur-

pose. On this occasion, lands were offered to settlers so low as twopenny per acre. At this period, and on these terms, Sir Walter Raleigh and others obtained grants. On the flight of Tyrone, and those who had espoused his cause, more than 500,000 acres were to be disposed of in the six northern counties. As abuses had arisen from the grants having been too large on former occasions, they were made considerably smaller at this time. The Corporation of London obtained its large possessions in the county of Derry by this forfeiture. The forfeited lands in the time of Cromwell, were appropriated chiefly to the discharge of the arrears due to the English army. Connaught was entirely reserved for the Irish. After all these assignments, however, the counties of Dublin, Kildare, Carlow, and Cork, were still unappropriated, and these were reserved to be disposed of as parliament thought proper.

On the Restoration, the act of settlement, and the subsequent bill of explanation, (both of which have been adverted to in the history,) were passed, for the purpose of regulating and assorting the grants. In the reign of King William, forfeitures were made to the extent of upwards of one million acres, and of the value of upwards of £200,000 a-year. By the articles of Limeric and Galway, part of these forfeitures were restored; but it is calculated, that the gross value of the estates forfeited, from the 16th of February 1688, and not restored, amount to upwards of one million and a half.

The tenure of landed property in Ireland differs, in one respect, very considerably from that by which land is held in England; for, with but two exceptions, there are no manorial rights in Ireland. The income of estates varies very much—from the lowest value to upwards of £100,000 per annum. There are several estates that reach upwards of 50,000 acres. It was formerly a common practice, to grant leases for ever, or for 999 years, or renewable for lives on a payment of a certain fine. Hence the property of very extensive estates at present, is vested in those who receive very little rent from them. In Ireland, landlords never erect buildings on their estates, nor expend anything in repairs; and the leases, in general, contain very few clauses. Six months credit is generally given on the rents, which renders the tenant very dependent on the landlord. In many leases the tenant is bound, besides Leases, paying his rent, to labour for his landlord at an inferior rate of wages. The system of what are called “middle men,” prevails very much in Ireland: These are persons who rent land from the proprietors, and let them again to the real occupiers. Sometimes there are several renters between the landlord and the occupier; and the latter is answerable, not only for the rent to the person under whom he directly holds, but also for the rent due by each renter to the person above him, and by the first renter to the proprietor. This system arises from the poverty of the Irish farmers in general; but it evidently not only proceeds from poverty, but tends to increase it. The leases commonly granted, are 61 years and lives—31 years and lives—21 years and lives—and 21 years; according to Mr. Wakefield, or £1, 7s. 1d. Irish money per Irish acre. Rent.

In some counties, the green, or cultivated acres, average from £2, 10s. to £3, 8s.; the latter is the case with the pasture land of Limeric, whereas the green acres in Mayo and Fermanagh do not average above £1, 5s. In some parts of Ireland the value of estates is at 30 years purchase; in general it does not exceed 20; and in some places it is not more than 16 or 18.
In considering the agriculture of Ireland, it will be proper to divide it into three parts. The arable husbandry, the dairy husbandry, and the grazing husbandry. The general character of all the three kinds, particularly of the arable husbandry, is very low.

That the agriculture of Ireland has improved much within these few years, is evident from the greater supplies of corn which she has been enabled to export to Great Britain. On this point, the Report of the Committee on the Corn Trade, which sat in 1813, is decidedly satisfactory. This committee put certain queries to the Farming Society of Ireland; and the following is their report of the answers to these queries, and of the result of other investigations which they entered into on the same subject:

"The answers of the Farming Society of Ireland, to the queries of the committee, shew, that there has been a very considerable increase of tillage in that country in the course of the last ten years; estimated, by many skilful persons, at nearly-one-fourth. That the land already in tillage is capable of being rendered much more productive—that the same land in some parts, upon which formerly seven barrels of wheat the acre was considered a good return, now yields, by better management, (without the loss of two seasons rent and labour under the system of open fallow,) at least ten barrels the acre; and that there are very considerable tracts of land now in grass fit to be converted into tillage; almost all the meadows and pastures which are dry and free from rock, being capable of producing a crop of lea oats with one ploughing, and of being made productive afterwards, by rotation crops, in the usual way.

The evidence of several persons, well acquainted with Ireland, concurs in proving, that the tillage of Ireland has of late years increased very much, and is capable of being still further increased. Of the actual practicable increase, it is impossible to form any correct opinion; but when all the various circumstances are taken into consideration, which exist in Ireland favourable to such an increase, the production of a much greater quantity of corn may be expected, than would be sufficient to provide for the average deficiency (calculated upon the importation for the last ten years) of the produce of this country to supply its own wants.

The following comparison of the prices of corn in Ireland, coupled with the value of corn exported from thence in the last year, £2,938,180, affords a striking practical illustration of the foregoing reasoning:

<table>
<thead>
<tr>
<th>April 1812</th>
<th>April 1813</th>
</tr>
</thead>
<tbody>
<tr>
<td>of 20 stone, was 3s. 6d.</td>
<td>6s. 6d.</td>
</tr>
<tr>
<td>of barley, per barrel of 16 stone, 4s. 9d.</td>
<td>5s.</td>
</tr>
<tr>
<td>of oats, per barrel of 14 stone, 3s. 4d.</td>
<td>3s. 8d.</td>
</tr>
</tbody>
</table>

It is worthy of observation, how much larger the proportion of corn imported into Great Britain from Ireland, is to the whole of the corn imported into Great Britain in the last five years, than it was in the preceding 16 years.

In the last five years, the value of the whole imported was £18,934,359; of this was Irish corn £6,507,884, being something more than one-third of the whole.

In the preceding sixteen years, the value of the whole imported was £4,585,787; of this was Irish corn £6,379,027; being £616,075 more than one-seventh of the whole.

Tillage husbandry forms a small part of the agriculture of Ireland. In consequence of the village-partnership system, which prevails in the western counties—the small manufacturing farmers in the eastern parts of Ulster—the small subdivisions of property throughout the greater part of the southern coast—the large tracts of mountains—and the extensive grazing pastures and dairy farms in other parts of Ireland, there is little room for tillage husbandry. This husbandry varies so much in different parts of Ireland, that Mr. Wakefield, in order to give a clear and accurate idea of it, divides the whole country into nine districts.

In the first district he comprehends the flat parts of Antrim, the eastern side of Tyrone, Down, Armagh, Monaghan, and Cavan. In this district the farms are extremely small; in consequence of which, the land is generally dug with the spade. Potatoes, flax, and oats, are the crops commonly cultivated; and these are grown till the land is exhausted, when it is cultivated by the cow, the goats, two or three sheep, and the poultry lying upon it for some years. The ploughs used in this district are of the most rude and imperfect structure, and do their work in the most slovenly manner. When a plough is used, three or four neighbours unite their strength, each bringing his horse, or his bullock, or his milch cow. Most ploughs are attended by a person, whose employment it is to turn back the furrow, which would otherwise revert to its bed. All the other operations of agriculture are performed in this district in the same rude manner. The little wheats that is raised in it, is "lashed"; that is, the grain is knocked out by striking the sheaf across a beam placed above a cloth; it is, however, afterwards threshed with a flail.

In this district, as well as in the greater part of Ireland, the corn is threshed on the highways, and is dressed by letting it fall from a kind of sieve, which, during a great strong wind, is held by a woman as high from the ground as her arms can reach.

Under the second district, Mr. Wakefield comprises the northern part of Antrim, Londonderry, the north and west of Tyrone, and the whole of Donegal. Tillage here is in a much worse state than in the first district. There is no clover; and, with the exception of a little near Derry, no wheat.

The third district comprehends the northern part of Fermanagh. Here the farms are much larger than in either of the former districts, the agriculture better, and the crops more productive. Some wheat is grown, but oats are the most prevalent crop. A small portion of the land, however, is only employed in tillage.

The fourth district comprises Sligo, Mayo, Galway, Clare, and parts of Roscommon, and Longford. In some parts of this district, the spade culture is generally pursued; but in other parts the land is cultivated with the plough, drawn by four horses abreast. In Roscommon, the practice of yoking horses to the plough by the tail is still followed, at least with two-year-old colts in the spring. Oats are chiefly raised in this district; but along the sea-coast of Sligo considerable quantities of barley are grown. A large portion of this district is let on partnership-leases, according to the village system.

In the fifth district, which comprehends Limerick, Kerry, the south-west and northern parts of Cork, and part of the county of Waterford, little corn is grown, with the exception of the southern part of Cork.

In the sixth district, which takes in the remainder of Cork, most of the land is in pasture; and, where it is in tillage, the spade is generally used. The seventh district comprehends some parts of Tip-
IRELAND.

The forming. It is generally conceded that the Irish plough has been already adverted to. It is made chiefly of wood, with a very long beam, without a swillyard: the breast, which is also of wood, has seldom any ground; and the share has hardly any wing. In Wexford, the beam is shorter than in any of the other counties, and the share in general is of cast iron. The Scotch plough has been introduced into these few years. The flail is seldom heavier than a schoolboy’s whip. The spade is much narrower than the English spade; the handle generally five feet long; the handle of the shovel is still larger, it is sometimes rounded, sometimes pointed, and often square at the end. The loy, which is much used in Ireland, is a long narrow spade, which projects entirely on the right side of the handle; its breadth is that of the foot. The slane is a double loy, used in cutting turf. The sliding cars have no wheels; the ends of the shafts are shod with iron, with a wicker basket suspended between them. Cars are small carts, having the wheel fixed to the axle-tree, which turns round along with the wheel. The wheel is not spokeed, but solid. The cars are difficult to be turned.

Little labour is bestowed on fallows in Ireland; and that little is very ill done. Three ploughings are deemed amply sufficient; and in consequence of these being performed with a rude and inefficient plough, not followed by the other necessary operations, the ground is generally full of weeds. The Irish, however, bestow a great deal of labour in trenching their land. By this operation they turn it into beds, and shovel out a deep trench between them, throwing up the earth; this is done to all land, whether ploughed or dug, while the crop is growing: the expense is eight shillings per acre.

When Boate wrote his natural history of Ireland, wheat appears to have been cultivated only in a very partial manner in the province of Connaught; and from the account which has been given of the agriculture of Ireland in its different districts, it will be seen that, even at present, its cultivation is very limited. There is little or no wheat grown in the counties of Monaghan, Tyrone, Derry, Donegal, Sligo, Mayo, Leitrim, or Cavan; the principal wheat districts are the counties of Kilkenny, Carlow, Dublin, Meath, Louth, and parts of Limerick, Tipperary, Clare, and Cork. The red Laminas is the kind most in use. Spring wheat grows well near the sea coast of Wicklow. Wheat is generally sown after potatoes, or a fallow; little attention is paid to it while growing. The Irish wheat is for the most part coarse, and of inferior quality; in consequence either of the weather of the climate, or bad harvesting, it all requires to be kiln dried. Barley is by no means generally cultivated in Ireland; it is of inferior quality to that grown in England, not yielding so much saccharine matter by 20 per cent. Where barley is cultivated it is sown after potatoes. Bere, or big, is grown in Kilkare, Meath, West Meath, Longford, and in the north on cut-out bogs. Meslin, or a mixture of wheat and rye, is sown near Drogheda, at the market of which it finds a ready sale.

Of all the species of corn, oats are the most extensively cultivated: forming the principal part of the food of the people, a market for them is every where to be found. It is calculated, that throughout the whole kingdom, there are ten acres of oats for one of any other species of grain. They are sown after wheat, potatoes, flax, and barley; and even year after year in succession, till the land is quite exhausted. In the mountainous districts, the black oat is generally sown; of late years the potato oat has been introduced into the lower grounds. The Irish oats are not equal in weight or quality to the English. Beans are cultivated no where except in parts of the county of Wexford. Rape is
Ireland has long been celebrated for the immense quantities of potatoes it produces, as well as for their excellent quality. They are planted on every kind of soil, either in drills or on lazy beds. The former method has been introduced lately, but it is gaining ground fast. In general the potatoes are stored up by the poorer classes in their cabins; where they are in large quantities, they are pitted in the fields where they grow. A potato pit, lined with turf, is deemed preferable to one lined with straw. Potato land rents from £6, 6s. to £10, 10s. per acre; the whole expense of growing them, including rent, varies from £13 to £16 per acre. The produce varies very much; perhaps from 40 to 50 sacks, of 20 stone to the sack, and 21 lbs. to the stone, may be deemed unusual produce on good land.

Flax is cultivated through almost the whole of Ireland, except Wicklow and Wexford; but it is principally grown in the province of Ulster: it follows potatoes, oats, and barley. The plough is seldom employed; the ground, for the most part, being prepared by the spade, but the earth taken from the trenches is not always shovelled over the beds.

The culture of hemp was formerly pretty extensive on the rich lands in the county of Limeric; but it is now abandoned there; nor has it succeeded in other parts in any considerable degree, notwithstanding government afforded premiums for that purpose. The quantity of land sown with hemp, as returned to the Linen Board in 1808, was only 395 acres.

Of the indigenous grasses of Ireland, it does not seem necessary to specify any, except the fiorin grass, or agrostis stolonifera, which has been lately very highly extolled by Dr. Richardson. Its merits, however, are not nearly so great as he represents them; and, indeed, the only situation for which it is adapted, is sea-walls, where its roots run and bind them together.

Hay. Considering the very imperfect and backward nature of Irish husbandry, it is not to be expected, that laying down land to grass is well understood. In fact, it is seldom done now; but, in most places, the ground is suffered to clothe itself with its natural herbage. Soon after grass is cut for hay, it is formed by the hand into what are called "lap-cocks," each of which is as much as a woman can twist round her arms like a muff; these being laid on the ground in the direction of the wind, which blows through them, are soon dried; and are then put into a "tramp-cock." In this state it becomes heated, and its quality is further injured by the heated hay being put into ricks, so that the quality of by far the greater part of Irish hay is very indifferent.

From the account of the arable husbandry of the different districts, it has already been seen that very little clover is cultivated. In the west and south-west, it is scarcely known; and, according to Mr. Newenham, there are not 5000 acres in the whole island; where it is cultivated, it is sown on exhausted and foul land. There are few quickest hedges in Ireland. In the limestone districts, stone-walls, and in the other districts, earthen banks are the usual fences. In the southern counties, furze is sometimes planted on these banks.

The dairy husbandry is the most extensive, and the best managed in Ireland. Kerry, Cork, Waterford, and parts of Kilkenny, Carlow, Meath, West Meath, Longford, and Fermanagh, as well as the mountainous parts of Leitrim and Sligo, are principally occupied by dairy farms. Butter is the only produce: a great deal is also made on the small tenures in Cavan, Monaghan, and Down. The method practised in Dorsetshire, Devonshire, and other counties in the west of England, of letting dairies to dairymen, at so much a cow per annum, is followed in the south of Ireland. The average number of cows on a dairy farm is about 30 or 40; three acres of land, of middling quality, are deemed necessary for the subsistence of each cow. The average produce of milk is 8 quarts in 24 hours in summer; and 5 quarts in winter; four good cows will give half a cwt. of butter in a week. The best butter is made in Carlow, and the worst is produced from the rich soil of Limeric and Meath. Butter of the first quality is sent to England, where it is either consumed or shipped for the East and West Indies; the next sort is sent to Spain, and the third to Portugal. The fattening of calves for veal is little practised in any part of Ireland.

The grazing husbandry of Ireland is not, as in England, land, united with the tillage husbandry; nor are there large tracts of land, exclusively devoted to the breeding of cattle, as in the Highlands of Scotland. The mountains of Ireland, instead of being grazed by those who farm them, are frequently let, on a partnership-lease, to the inhabitants of a neighbouring village, each of whom turns a certain number of cattle, horses, goats, or geese, according to the rent he pays. The few cattle that are fed on the mountainous districts, are generally very poor. The most extensive and valuable lands for fattening cattle are in Munster, viz. the Caucuses on the banks of the Shannon and Fergus, and in parts of the counties of Limeric and Tipperary. Some parts of Cork, Queen's County, West Meath, a small part of Louth and Kildare, also contain rich grazing land.

The native Irish cattle are nearly extinct: they are Cattle narrow in the loins and thin in the quarters; with short legs, large bellies, and white faces. The Kerry stock are a distinct breed. The Holderness, Staffordshire, and Devonshire breeds, are the principal ones which have been introduced from England; the Staffordshire is the most common on the grazing lands, or rather a mixture of the native Irish and the Staffordshire.

A greater extent of country is employed in Ireland for the grazing of sheep, than for the grazing of bullocks. Roscommon, Galway, Clare, Limeric, and Tipperary, are the great breeding counties for sheep. In the province of Ulster there is not a single breeding flock. Galway, Clare, Roscommon, Tipperary, and Meath, are the principal fattening counties. Mr. Wakefield says, that in the whole course of his tour, he never saw a sheepfold; and only once sheep feeding on turnips. The native Irish sheep are small, and are covered with nearly as much hair as wool; but they are now not common. In consequence of their having been crossed with different kinds of English sheep, the Irish sheep at present, are of the polled, long-woolled kind, and, in the great breeding counties, very large. In many parts of Ireland, they are kept only for their wool, and this only for the use of the family. A breed of fine woolled sheep, peculiar to the mountains of Wicklow, exhibit the only traces of a distinct race of short woolled sheep in the island.

The native Irish horse is a very useful animal: it is seldom exceeds 15 hands in height, and is very hardy and sure-footed. This breed is very much used by the linen-merchants of Ulster, in riding from market to market. A large, long, blood horse is much reared in Meath, and is to be found in most of the rich grazing counties. But the horse, usually employed for all kinds of labour in Ireland, is the one first described.
not kept. Those belonging to the cottars, are generally
confined by a tether to the tops of the banks. In
the mountains, where they are numerous, they are quite
at liberty. Many of the poorer families have no other
milch but what their goats afford. The Irish breed of
hogs is very tall, long, and narrow in the loins. They
are met with in every part of the kingdom. No peas-
ant is without one. They are fattened principally
with potatoes; and afterwards sold, for the purpose
of paying the rent. Breeding sows are generally kept by
dairymen. Rabbit wars are not numerous in Ire-
l; but some of them are very extensive. On the
east side of the river Bann, there are two, one of which
contains 500 acres, and the other about 2000. It is sin-
gular, that the hair of the hares in Ireland will not felt;
whereas the rabbit hair in that country, answers re-
markably well in the manufacture of hats.
Bees thrive remarkably well, on the dry hills in the
county of Down, and the honey there is highly esteem-
ed for its fine flavour; but the breeding of them is
much on the decline in this county as well as in Kil-
kenny, where formerly a considerable quantity of mead
was made. The county of Wexford is celebrated for
crammed fowls; and there is a fair at Ballyheaghe, in
that county, expressly for the sale of poultry of all
kinds. Families send thither from a great distance, to
purchase store fowls. Turkeys are numerous in Ire-
l; the warmth of the cabins, into which they are
always admitted, is favourable to their increase. In
the county of Cork, there is a fair for a sale of them.

CHAPTER IV.

Manufactures—Linen—Cotton—Wooden, &c.—Distilla-
tion—Flour Mills—Salting Provisions, &c.—Fish-
ery—Trade and Commerce—Revenue and Finance.

The linen manufacture is very justly considered as
the staple manufacture of Ireland. It was established
by the Earl of Strafford, when he was lord lieu-
tenant of this country, in the reign of Charles I. In order
to fix it on a firm foundation, he brought flax seed from
Holland, and spinners and manufacturers from the Ne-
thelands and France. His lordship himself afterwards
embarked in the business, and expended £50,000 of
his private fortune.

In consequence of the civil wars between Charles and
his parliament, this manufacture languished, and had
almost been annihilated, when the Duke of Ormon
d gave it his patronage, and took measures for its re-es-
ablishment. His measures were successful; and, as he
sent persons into the Netherlands to learn the best
mode of raising flax, and procured manufacturers from
Brabant, France, and Jersey, it was soon placed on a
better and firmer footing than it had ever been. The
places where the manufacture was first carried on in
the Duke of Ormond's time, were near Dublin, where
cordage, sail cloth, ticking, and linen of Irish yarn,
were manufactured, of excellent quality; and at Car-
rick. Before he quitted the government of Ireland in
the year 1669, the linen trade was fully established,
and in a promising condition. In the beginning of the
next century, parliament took it under its protection;
considerable sums of money were voted for its support;
a board of trustees was established; and bounties were
granted on the exportation of Irish linen. In 1787,
the board exerted themselves in the introduction from
France; and establishment in Ireland, of the cambric
manufacture.

The raw material for the linen manufacture, is al-
most entirely grown in Ireland. The following Table
shows the number of acres sown with flax in the year
1810. It does not include pieces of land less than an
acre sown with flax. Hence it may fairly be calcu-
lated, that the total number of acres under this plant
in the year 1810, was about 160,000, which, allowing
the average produce to be 30 stone per acre, at 10s. 6d. per
stone, the average price for the seven years before
1810, will give an annual produce of the raw material
worth £1,500,000.

</table>

Till the beginning of the present century, the flax Spinning,
was entirely spun by the hand. Spinning by machin-
ery was first introduced in the county of Down, and
afterwards spread into other counties; but it is by no
means general. This has arisen principally from the
very low price of labour in every part of the land. Yarn
spun by women, is sold in this country much cheaper
than the same article manufactured by machinery in
England. The earnings of the poorer females are fre-
quently not more than two-pence a day, working
diligently from morning to night. There is also an-
other reason why machinery has not been more gener-
ally established. It cannot with any material, however
fine, exceed the fineness of three hanks in the pound;
whereas women, when the flax is good, can spin it from
twelve to twenty hanks. "To sum up the whole,"
observes Sir Charles Coote in his Survey of Monaghan,
"the quantity of yarn spun by machinery, the greater
price given for it, and the better means of obtaining a
market, are in favour of that mode with respect to
woollen yarn. On the other hand, the low price of la-
bour, the superior fineness of the wrought material,
and the expense of machinery, with its wear and tear,
are very great drawbacks; yet it may be estimated, that the
balance is in favour of the former, to the amount, it is
The Irish women have long been celebrated for their skill in spinning yarn. This is supposed to arise from their labouring little with their hands, and hence having their fingers very supple and soft.

In many parts of Ireland, the manufacture is confined to spinning yarn, which is sold to the weavers at established markets; but, in several instances, the flax is grown, prepared, spun into yarn, and manufactured into linen, by the same person and his family. If, however, we look to the country in general, those who grow flax, are much more numerous than the spinners. This appears by the exportation of unspun yarn; and the spinners are more numerous than the weavers, as appears from the exportation of linen yarn.

The earnings of the weaver depend partly on his skill and industry, and partly on the fineness of the linen which he weaves. The looms they employ cost from four to five guineas each; many houses have three looms; one third of a pound of tallow is required to dress a web. Children are hired to attend a loom, at from 13s. to 17s. the half year, with diet, washing, and lodging: in some cases journeymen are employed, at eight guineas per annum, with board and lodging. The weavers estimate, thus, when working ten weeks, they gain 10s. 4d. a week, and if they worked every day, could weave a web in a week: this, however, must depend on the fineness of the linen. The average earnings of a linen weaver may, perhaps, be estimated at 7s. a week.

The linen manufacture flourishes most in Ulster; but it is established also in Galway, Mayo, and Sligo, and towards the south, in the whole neighbourhood of Drogheda; it exists also in some places in the King's County, Kerry, and along the coast of Carlow; in fact, with the exception of Wexford and Wicklow, where it is unknown, it prevails, more or less, over all the other parts of Ireland. Linen is woven of different widths, from 10 inch bundle linen, made at KERRY, to 5-4 sheetings manufactured near Cootebill; and of different qualities, from coarse, thin, 3-4ths wide, manufactured in Antrim, which sells for 8s. per yard, to cambrics, worth one guinea per yard. The manufacturing of linens of certain widths, seems confined to certain districts. Narrow linens, not exceeding, when bleached, 92 inches, are manufactured in Donegal, Londonderry, Tyrone, and Antrim; in this last county also are made all the 3-4th wide linens. The fine yard wide, or cambrics, lawns, and diapers, are made near Belfast, Lisburn, and Largan; in Armagh, coarser yard wedges. In Cavan are manufactories for thin linen, for the most part 7-8ths wide. Fermanagh and Sligo, manufacture 7-8ths. A strong kind of 7-8ths dothes; some 9-8th and 5-4th sheetings, are made in the counties of Louth, Meath, and Dublin. A coarse cloth, like the Scotch Osnaburghs, is manufactured in Kerry and Cork; it is exported for negro clothing. There is a damask manufactory at Lisburn, and a manufacture of calico cloth in the county of Cork. Most of the bleach-greens, which finish for sale those linens that are sent in a bleached state to England, are in the counties of Fermanagh and Sligo. The bleachers are distinct persons from the manufacturers; the latter carry their webs to market, where they are purchased by the former. It is calculated that every bleacher in the county of Londonderry, furnishes, on an average, 5000 pieces annually; so that, on the supposition that there are 50 bleachers, the pieces bleached in this county will amount to 250,000; and, at £2, 5s. 8d. the piece, the total value will be £562,500 Sterling. On the Bann, which is the principal river in the county of Down, there are 20 bleach-greens, which bleach on an average 8000 pieces annually, or 160,000 pieces; the value of which is estimated at upwards of half a million.

The quantity of linen sold in Dublin, in 1808 and 1809, will be seen from the following statement, extracted from the Appendix to the Linen Board Report.

192

The cotton manufacture is of very late introduction. Cotton ma- into Ireland. The first mill for spinning cotton twist by water was erected in 1784; and, in the year 1800, will appear, in evidence before Parliament, that the cotton manufacture, established within a circle of ten miles round Belfast and Lisburn, and including those towns, employed 13,500 working people; and that the whole number, to whom it gave occupation, amounted to 27,000. This manufacture is spreading rapidly, and seems as if it would supplant that of linen in many parts of Ireland. Being similar, in some respects, to the latter, it made its way with greater facility among the lower classes. It also affords them higher wages, principally from the manner in which it is carried on; for, instead of the raw material, as in the case of the linen manufacture, being purchased by the weaver, and sold afterwards in a manufactured state, the cotton-yarn is either given out by the master manufacturer to the weaver, who receives so much per piece for his labour, or is woven in manufactories. All the spinning is performed by machinery. The cotton manufacture is established chiefly near Belfast, where it was first fixed. It has also spread to Dublin, Kildare, Wicklow; Wexford, and Louth. At Collo, in Louth, there are 1500 looms employed in calico weaving; and at Stratford, in the county of Wicklow, there is also a large calico manufactory; the yarn for this is brought from Scotland, and wound and wove in the village. The manufacture of muslins is also carried on in some parts of the counties of Cork, Down, and Queen's County; and, indeed, it is highly probable, that all the branches of the cotton manufacture will fix themselves in Ireland, especially in those parts where linen is made; from the great and obvious advantage which is derived from the similarity of the manufactures, in enabling the weavers to turn their labour to the one or the other, as he demand for either is more prevalent.
In treating of the sheep husbandry of Ireland, it has been remarked, that the demand for them as mutton is very limited; consequently not very many are kept, and of those that are, a considerable proportion are exported to England. Hence it will appear, that the woolen manufacture, on a large scale, cannot exist in Ireland. We have already mentioned, in the history of this country, that it was formerly much checked and depressed by the jealousy of the English woolen manufacturers, to which the English government very unjustly, as well as unwisely, gave its sanction and support. And, since the union, which placed the two countries on the same footing, this species of manufacture does not seem to have flourished. Besides the cause already mentioned, which perhaps ought more properly to be deemed the effect of the absence of woolen manufactories, there is another which operates very powerfully and generally. The great mass of the people manufacture their own woolen cloths. All the wool that is shorn is manufactured into frieze and linsey by the proprietors of the sheep, who card, spin, weave, dye, and consume it. The poorer classes, who cannot afford to purchase oil for their woolen goods, extract, in the summer, the juice of the fern root, which answers the purpose of oil; and the twigs of the elder, walnut, and oak, with elder berries, &c. are used for dyeing. In some parts of Ireland, the common farmers and cotters, and their wives and children, manufacture not only frieze, stockings, linseys, flannels, petticoats, &c. for their own children, but also some woolen goods for sale.

As the woolen manufacture on a great scale is not established in this country, there are few or none of those people who, in England, prepare the wool for the manufacturers. There are no wool breakers. There are plenty of wool merchants, who buy whole fleeces, but none who understand the art of sorting it. As the exportation of wool in the yarn is permitted by the Irish laws, the principal part of the wool, not used in the domestic manufactures, is purchased by the merchants in the south of Ireland; and after it is spun there, it is exported to England for the Norwich manufacturers. There are, however, a few woolen manufactories of different descriptions in some parts of this country. A small quantity of broad cloth is made at Carrick on the Suir; blankets are made at Kilkenny; but both these manufactures are on the decline. In 1800, there were employed at Kilkenny about 780 people; the average number of pieces woven in the year 1818 was 2500, and the greatest capital at any time employed did not exceed £39,000. There is a flannel manufacture in the county of Wicklow also on the decline. Between 1794 and 1800, the total number of pieces exposed to sale scarcely exceeded 55,000. A small quantity of broad cloth is manufactured at Dublin; and very lately, in the county of Kildare, a woolen manufacture has been established with shearing machinery, and all the other improvements of Yorkshire. Broad cloth and blanket manufactories are established nowhere to the north of the capital. In the north-western counties, and along the coast of that country, stuffs are manufactured.

Gloves, &c.

Gloves are manufactured in some parts of Ireland. What are called Limeric gloves are made of the skins of calves taken from fat cows. Iron is not manufactured to any considerable extent at present; though it appears, from Boase, that, in the middle of the 17th century, there were several very large iron foundries and manufactories in various parts of Ireland. Hardware articles are manufactured in Dublin; and reaping hooks, scythes, shears, and other coarse implements at Carlow.

This country has long been celebrated for its distilleries. Distilleries, both legal and illegal. The latter prevail most in the northern and north-western counties, and even in some of those to the south-west. The following table contains the number of unlicensed stills that were seized in the course of five years, from June 1802, to June 1806:

The number of fines imposed on Townlands for illicit distillation in the year 1814 were 3555, and the amount of fines was £90,210. The greatest number and amount were in the counties of Donegal (757), Cavan (501), Galway (363), Leitrim (325), and Sligo (304). The whole receipt of duty on home-made spirits, consumed in Ireland on an average of the years 1802 and 1809, was about £60,051; whereas it is supposed, if duty had been paid on all the home-made spirits, it would have amounted to upwards of £3,250,000. The principal licensed distilleries are established at Limeric, Cork, Ross, Dublin, and Drogheda. In the year 1813, the largest distiller in the kingdom made 17,000 gallons of spirits per week, and worked his stills between nine and ten months in the year. Distillation was first carried on in the north, and has been introduced into the south only within these 30 years. The following table will further illustrate the state of legal distillation in Ireland:

Public breweries have been introduced into Ireland only within these few years. At present, the principal breweries are at Cork, Fermangh, Limeric, Waterford, Roscommon, Dublin, Belfast, Cavan, Armagh, Doneghmore, Dunbarvon, &c. Malt is prepared by the brewers themselves, and never purchased by maltsters. One of the largest breweries in Ireland brews upwards of 100,000 barrels per annum. The following Table shows the quantity of malt used in the breweries and distilleries for several years.

* During the greater part of this year distillation from corn was suspended.
† Suspension of distillation from corn, and continued during the first quarter of this year. From the 28th of September 1860, to the 5th February 1817, there were 335,947 barrels of corn, 12 shillings to the barrel, used in distilling.
Account of the Quantity of Malt for which Duty has been paid in Ireland, in each of the last Ten Years, to 5th January 1813.

In the south of Ireland, there is some cider made. That made in Clare is of excellent quality: it is manufactured from the cockeage apple, which grows principally near a town in that county, called Six-mile-Bridge, not far from the sea, and in a part of the country where frost and snow are unknown.

In consequence of wheat bread being more generally used than it was formerly, flour-mills are more common. When Mr. Young was in Ireland, between thirty and forty years ago, there were no flour-mills to the north of the river Boyne; now, there are several. Armagh, Belfast, and Derry, have mills; but there are none to the north-west of Navan. They are numerous, and very large, on the Blackwater, near Navan, some of which grind from 15,000 to 21,000 barrels per annum. Flour-mills abound in the south of Ireland.

In times of war, Ireland is distinguished for its extensive dealings in the provision trade. The principal part of this trade is confined to the city of Cork. During the last war, the average number of oxen slaughtered was about 10,000, and of cows 8,000. In the time of the American war, the number of bullocks slaughtered in Ireland annually was 50,000: last war they were not nearly so many, principally arising from a greater number having been exported alive. In 1807, 50,000 hogs were slaughtered in Cork. Bacon and hams are salted, on an extensive scale, at Limerick, Clonmel, and Waterford. One half of the hides of the cattle slaughtered at Cork are exported; the hoofs are also exported, and made, at Birmingham, into snuff-boxes. The hens are made, in Ireland, into lanterns, combs, &c. Glue is manufactured, at Limerick and Cork, from the ears, &c. of bulls. A great deal of bone is converted into ivory-black, particularly at Dublin. On the western coast, large quantities of kelp are made; it is used by the Irish bleachers. There are manufactories for making vitriol, muratic acid, and Glauber's salts, at Lismore, Belfort, and Moyellan. At Dublin, Waterford, and Belfast, there are glass manufactories. Sugar is refined at Dublin and Belfast. There are salt-works at Sligo and Dungarvon; and Cheshire rock-salt is refined at Waterford.

The principal fisheries in Ireland are those of herrings and salmon; the herrings caught off the coast near Galway, are particularly large and fine; this fish is exported from Ireland to Spain, Portugal, Italy, the West Indies, North America, and France. Londonderry, Colerain, Dublin, Waterford, Limerick, and Drogheda, are noted for producing fine salmon; but the north of Ireland abounds more in this fish, and the fisheries there are more valuable than in any other part of the kingdom. The salmon fishery on the Bann, near Colerain, is particularly celebrated. In the year 1760, no less than 320 tons were taken in this fishery; and in a single draught, there were once 840 fish caught. The mouth of the Bann faces the north; and hence is well situated for receiving the fish that roam along the coast in search of fresh water. In this river they fish with nets 18 score yards long, and are continually drawing night and day, during the whole season; two sets of 16 men each alternately relieving each other. The best fishing is when the tide is coming in. The famous salmon leap, or fishery on the Bann, lets for £1000 a-year. The main stream is always left open for the free passage of the fish up the river; but on the 12th of August, the fishery ceases here, (as it does all over Ireland,) and all the other weirs are opened. At this leap, the salmon are caught in a trap of basket-work. The fishery for salmon at Ballyshannon, on the river Erne, is, perhaps, the most productive, after the fisheries on the Bann: the rent is about £1100. There is also a productive eel fishery here.

In the south of Ireland, particularly on the Blackwater, the mode of fishing is different from that followed in the north; and is thus described in the statistical survey of Kilkenny: "The country people catch salmon with a snap-net suspended between two cots, which are small boats, flat-bottomed, narrow, equal at both ends, and governed by paddles. Two men are in each boat, one of whom conducts it; and when the fishers find the net drawn, the boats are closed immediately." At almost all the places where salmon are taken, the fish is smoked by means of turf fires, which communicate a pleasant flavour to it, and render the Irish salmon a valuable commodity in many foreign markets. The Carlingford oysters have already been noticed; the demand for these oysters is so great in Ireland, that none are left for exportation.

The commerce of Ireland was most unjustly shackled Commerce, till the year 1780; and even then was not placed on a fair and equitable footing. The Union, however, has given to this branch of the empire, with respect to commercial privileges, what they ought always to have had. Ireland imports from Great Britain, iron, hops, shot, pepper, tea, pearl-ashes, seeds, tobacco, spices, indigo, dyes, colours, alum, cotton wool, logwood, silk, calicoes, earthenware, hardware, beer, sugar, coffee; cabinet and upholstered goods, hats, &c.; and exports to Great Britain, corn, hides, horse hair, provisions, butter, whisky, cattle, flax-seed, yarn, tallow, &c. The trade between France and Ireland is considerable; from France she imports wines particularly, and exports to France, provisions, linen, &c. Portugal sends her wines, particularly their port, and her fruits, &c., and receives provisions, butter, &c. The trade with Spain consists nearly of the same articles. The commerce between Ireland and the north of Europe is principally carried on through England. With North America and the West Indies, the trade is very extensive. To the former, Ireland sends her linens principally, and occasionally butter; and receives from it flax-seed, &c. To the West Indies, Ireland sends linens, provisions, &c., and receives sugars, &c.

In further illustration of the commerce of Ireland, we shall subjoin the two following sets of Tables. The first set exhibiting the export, in different years, of the principal produce, and manufactures of this country; and the second the imports and exports generally.

1. Linen Cloth.—The annual average quantity of linen cloth exported from Ireland from 1700 to 1750, linen was not 4,000,000 yards; from 1750 to 1755, 11,790,561 yards annually; from 1757 to 1763, 14,511,973; from 1764 to 1770, 17,776,802; from 1770 to 1777, 20,252,239; from the year 1756 to 1773, England was the market for nearly 9-10ths of the whole Irish exportation.

The real value of Irish produce and manufactures exported in the year ending 5th January, 1817, computed at the average prices current, amounted to £9,111,766. 6s. 9d.

The registered shipping of the several ports of Ireland, viz., Dublin, Cork, Youghal, Belfast, Newry, Wexford, Waterford, Kinsale, Limerick, Baltimore, Larne, Strangford, Drogheda, Donaghadee, Ross, Wicklow, Londonderry, Dundalk, Galway, Cobraine, Killbega, Sligo, Tralee, Newport, Ballyraine, was 1003 vessels, 54,262 tons, and 5,057 men, on the 30th of September, 1800.

### Ships which entered inwards.

#### Average of three years:

- **Ships:**
  - ending 5th Jan. 1805: 7843
  - 1811: 8983
  - 1815: 10,066

- **Tons:**
  - 1805: 611,935
  - 1811: 817,678
  - 1815: 955,351

- **Men:**
  - 1805: 14,140
  - 1811: 47,084
  - 1815: 59,594

#### Number of vessels belonging to the ports of Ireland, on an average of three years:

- **Ships:**
  - ending 30th Sept. 1790: 1076
  - 1800: 1009
  - 1810: 1116
  - 1815: 1146

- **Tons:**
  - 1790: 64,457
  - 1800: 51,355
  - 1810: 59,594
  - 1815: 59,099

- **Men:**
  - 1790: 2581
  - 1800: 1285
  - 1810: 28
  - 1815: 45

#### And the number and tonnage of vessels built and registered in Ireland, on an average of three years:

- **Ships:**
  - ending 5th Jan. 1790: 63
  - 1801: 20
  - 1811: 28
  - 1815: 43

#### Account of the number of vessels, with the amount of their tonnage, that were built and registered in the several ports of Ireland, in the three years ending 5th January, 1817, distinguishing each year.

Gross receipt, within the year ending 5th January, 1817, of the ordinary revenue of Ireland, £6,136,101: of which the customs produced £2,082,043, at a rate for collection of £30, 9s. 4d. per cent.; the excise produced £3,809,931, at a rate for collection of £15, 8s. 2d. per cent.; the stamps produced £691,179, at a rate of £9, 5s. 11d. per cent.; and the post-offices produced £2,360,417, at a rate of £59, 19s. 11d. per cent.

The principal custom duties were sugar, £1,141,241; tea, £314,600; and tobacco, £526,321. The principal excise duties were, strong waters, £118,617; malt, £389,792; tobacco, £560,731; licences, £59,077; and window duty £435,293. The hearth-money was £58,883; carriage duty £98,460; servants' duty, £54,909; and horse duty £99,235.

**CHAP. V.**

**Population of Ireland—Mode of Life and State of the Peasantry—Ecclesiastical State—Education—Government—Language—Antiquities.**

That Ireland has increased rapidly in population within the last half century; and that at present, considering the large portion of its surface, which is occupied by bogs, loughs, &c., its population is dense compared with that of most other countries in Europe, are circumstances the truth of which is generally admitted.

But, as no enumeration has recently been made of the actual number of people, we must rest content with the authority, or rather the opinion of those who have taken the most care, and possessed the best opportunities, to ascertain it. According to them, the population of Ireland nearly amounts to, if it does not really exceed, five millions. The first computation respecting the number of the inhabitants of Ireland, was made in the year 1695, by Captain Smith. According to him, they were 1,034,102. In the year 1731, there was a return to parliament of the number of inhabitants in each parish, and from this it appears, that in that year they amounted to 2,010,221. Since that, there has been no official return of the population; but there have been returns of the number of houses; and supposing six to each house, (which seems to be the average in Ireland,) there would be in the year 1794, 2,372,694 inhabi-
IRELAND.

Hence it will appear, that a very large portion of the inhabitants of Ireland are very poor. Those employed in the linen manufacture of Ulster, are comparatively comfortable; but the great mass of the people, especially the labourers in husbandry, and even the very small farmers, are sunk in ignorance and poverty. The pauperism is miserably ill-located. Four mud walls, with one entrance, and frequently without either window or chimney, constitute an Irish hovel. The rent of these cabins is from one to two guineas a-year. To each cabin, there is commonly annexed about one acre of ground, which is cropped with potatoes, oats, and flax.

There are numbers of the peasants who have not a bedstead, nor even a truckle bed-frame. They sleep on a bundle of straw, or heath laid on the clay floor; sheets are scarcely known; and their blankets are scanty and tattered. The rain not unfrequently descends through the thatch on their beds. Amongst their peculiarities of dress is their long coat; it is made of wool, and generally of a grey colour. Their food is almost entirely potatoes and milk; and their fuel turf. 'They are indisposed to labour; and in their habits far from clean. The wages of the agricultural labourers is not only very low, generally less than a day, but it is not unfrequently paid, partly at least, in kind, and not very regularly. The wages of the manufacturing labourers, is, in general, much higher. The children of the lower classes are seldom employed; but are suffered to go about dirty, idle, and nearly naked. Notwithstanding these disadvantages, which result from political causes in a great measure, the national character of the Irish breaks forth, even amongst the most ignorant and brutal of the peasantry. This national character is considerably different from that of Great Britain. "Greater vivacity, and quickness of parts, propensities more social, and stronger sensibilities of all kinds, accompanied by the usual attendants on such qualities, unsteadiness, and want of self-government, sufficiently mark them as a distinct people. Among the lower classes, there is often a ferocity, which breaks out in savage and bloody deeds, especially in their party and political quarrels; yet no people display more faithful and affectionate attachment to those who have conciliated their good will. A precipitancy of manner, and a prudence to exaggeration, have introduced into the conversation style of the Irish a kind of hurry and confusion, which has subjected them to the imputation of often falling into luttocious contradictions; but, on the other hand, eloquence is natural to them; and they display more information than their eastern brethren."!

The established religion of Ireland is the same as Ecclesiastical state, that of England. The kingdom is divided ecclesiastically, as well as civilly, into four provinces; but the boundaries of each do not coincide. An archbishop presides over each. The seven bishops of the northern province, are suffragans to the archbishops of Armagh, who is lord primate and metropolitan of all Ireland. The archbishop of Dublin is lord primate of Ireland; and has three suffragan bishops in the eastern province. The archbishop of Cashel, lord primate of Munster, has five suffragan bishops; and the archbishop of Tuam, lord primate of Connaught, presides over the three bishops of the western province. The province of Armagh contains ten dioceses: viz. 1. Archbishopric of Armagh. 2. Bishopric of Dromore. 3. Down. 4. 5. Connor and Derry united. 6. Raphoe. 7. Clogher. 8. Killmore. 9. Ardagh. 10. Meath. The province of Dublin contains five dioceses. 1. Archepiscopal of Dublin. 2. Bishopric of Killkare. 3. Ossory. 4. 5. Ferns and Leighlin united. The province of Cashel contains eleven dioceses 1. Archepiscopal of Cashel, and bishopric of Emly, united with Cashel. 2. 3. Waterford and Lismore united. 4. 5. Cork and Ross. 6. Clonfert. 7. 8. Limicet, Ardfert, and Aghade united. 10. 11. Killaloe and Killmore. The province of Tuam contains six dioceses. 1. Archepiscopal of Tuam. 2. 3. Bishops of Clonfert and Kilmacduagh united. 4. Elphin. 5. Killala. 6. Achonry. The number of deaneries is 33, and of archdeaconries 34.

But, though the established religion of Ireland is the Catholics, same as that of England, those who profess it bear but a small proportion to those who do not. The Catholics are far more numerous than the Protestants of all denominations. At least two-thirds of the whole population are Catholics; according to some three-fourths. And in the north and north-eastern counties of Ulster, the Presbyterians are much more numerous than those who profess the church of Ireland. The Catholics are by far the most numerous in Connaught, Munster, and the north-western counties of Ulster.

The means of education, which the great mass of Education, the Irish people possess, are very limited. As early as the reign of James II. free schools were erected in several of the large parishes. They have since been extended to some parts of the country. There is but one university, that of Dublin. There is also a college for Catholics at Maynooth, supported by government. But the state of education at present, will best appear from the following quotations from the last report of the commissioners of education in Ireland.

It appears, from these Reports, "that there are 33 endowed classical schools in Ireland (besides 14 of private foundation) the united emoluments of which amount to about £9,000 per annum, and the number of scholars educated in them to nearly 1000. " That, exclusive of the parish schools in the city of Dublin, and of other schools in different places, supported by private endowments, the number of which is 78,—there are 44 public establishments for the education of the lower classes, in which upwards of 9200 are lodged, maintained, clothed, and educated at an annual expense of about £70,000.

9 The following returns have been communicated to us from 17 dioceses out of the 23 into which Ireland is divided:
Ardagh and Tuam are united dioceses.

From the returns, it appears, that, exclusive of the charitable institutions, there are 3730 schools in these dioceses, in which are taught 165,67 children, of which number 45,590 are Protestants, and 116,977 Catholics. Of the schoolmasters, 1271 are Protestants, and 2455 Catholics.

"Hence we collect, that, as these dioceses may be estimated to contain four-fifths of the population of Ireland, the whole number of schools, including the parochial schools, amount to 4600—the scholars taught in them in 200,000, being an average of 48 to each school; and as these returns were made generally in the winter, when many children are unable to attend, and as itinerating schoolmasters, whose number is very considerable, are frequently not included in them, we are confident that more than 200,000 children, of the poorer class, receive annually, such sort of instruction as those schools afford.

"That instruction, except in a very few instances, extends no farther than reading, writing, and the common rules of arithmetic, and the prices paid are, on an average, 10s. per annum for reading, 17s. 4d. when writing, and £1, 6s. when arithmetic is added." (Fourth Report from the Commissioners of the Board of Education in Ireland.)

In the history of Ireland, the union of it with England has been noticed; and also the number of peers and representatives which, by that union, she is entitled to send into each house of the British Parliament.

The following Table exhibits the number of registered freeholds in each county, of the values of 40s., £20, and £50.

A viceroy, or lord lieutenant, still resides in Dublin, Governor to administer the executive government of Ireland. There are some minute differences between the statute and common laws of this country and those of England.

The Irish language is a dialect of the Celtic. It is Language spoken throughout the province of Connacht by all the lower orders, a great part of whom scarcely understand any English. It is also spoken very generally in the other provinces, except among the descendants of the Scotch in the north. It is supposed, that there are about two millions of people in Ireland, who are almost entirely ignorant of English. The music of the Irish is strictly national. It is distinguished by a pensive simplicity. "Few nations have given more undeniable proofs of a genius adapted to scientific and literary pursuits; but it is to be lamented, that the prevalence of dissipation has exerted so unfavourable an influence upon the general habits of life, that scarcely any European country is less distinguished by the productions of its press."

The principal antiquities of Ireland, are the castles; the cathedrals; the oratories, chapels, and round towers; the stone crosses; earthen works; and religious buildings. The round towers are singular buildings, supposed to have been erected about the ninth century. Of the religious buildings, the chapel at Cashel exhibits elegant and rich architecture, of remote and singular antiquity.

IRENEUS. Bishop of Lyons, is supposed to have been a Greek by birth, and to have been born near the city of Smyrna, about the middle of the second century. He acquired in his youth a competent acquaintance with the philosophy and literature which were then held in estimation in his native country; and, at an early age, was placed under the instruction of Polycarp, Bishop of Smyrna, who had been the disciple of the Evangelist John. Nothing more is known of his history till the year 177, or, according to others, 167, when he is found acting as presbyter of the church of Lyons in France, under Pothinus, who was bishop of that see. The church at Lyons had been planted at no very remote period, by missionaries from some of the Asiatic churches, and thus probably continued to receive pastors from the same quarter. In 177, when the persecution of the Christians, under Marcus Aurelius Antoninus, raged with great violence in France, particularly in Lyons and Vienne, an epistle, containing an account of their sufferings, was written to the churches in Asia, and is generally understood to have been drawn up by Irenaeus. Pothinus, the bishop, having suffered martyrdom in this persecution, Irenaeus was chosen as his successor about the year 179. In the following year, the death of Aurelius afforded a respite to the Christians, which continued with little intermission till the year 202, in the reign of Severus; but during this period of external peace, the Christian church was agitated by pestilent heresies of every description. Irenaeus applied himself, with the utmost assiduity, to detect the machinations and expose the errors of the corrupters of the faith; and to his unwearyed exertions in word and writing, it is principally ascribed that few of these false systems, though afterwards revived, obtained in his time a permanent footing. Between the years 180 and 192 he produced his celebrated treatise against heresies, which is the only one of his works now extant. It sufficiently proves him to have been a diligent investigator and acute reasoner, as well as a faithful defender of sound principles; and though the greater part of the tenets which he opposes may appear to modern readers too monstrous and absurd to have required a refutation, yet the merit of his labours cannot fairly be estimated by those who enjoy the advantages which flow from the diffusion of true science and the general circulation of the sacred Scriptures. About the year 190, when Victor, Bishop of Rome, revived the dispute respecting the observance of Easter, and attempted, in a most imperious manner, to impose the Roman practice upon the Asiatic churches, Irenaeus exerted himself, by letters to Victor and other bishops, to alyay the violence with which the matter was agitated, and to maintain the peace and unity of the church. The external tranquillity which had thus been preserved by animosities and contentions among the Christian pastors, was at length interrupted, in the beginning of the third century, by the persecution under Septimus Severus; which, though principally directed against Alexandria, was severely felt in other parts of the empire, and especially at Lyons, where the emperor is supposed to have formerly governed, when Pothinus was put to death. In this persecution, according to the testimony of Gregory of Tours, Irenaeus, after suffering with magnificent resolution various courses of torture, was finally put to death, according to some writers, in the year 202, when the emperor first published his edict, or, as others suppose, in 208, when he passed through Lyons in his expedition to Britain. The other works of Irenaeus, mentioned by Eusebius, were, a book against the Gentiles concerning knowledge; a description of the Apostolic preaching; a book of tracts; a letter to Victor, Bishop of Rome, concerning Easter, of which a fragment is preserved by Eusebius; a letter to Blasticus concerning schism; a letter to Horinus concerning the government of one God, of which some passages remain; a book concerning the number eight, addressed to the same Horinus, who had embraced the Valentinian heresy. See Mochelm's Church History, vol. i.; Lardner's Works, vol. ii.; Milner's Church History, vol. i.; Christian Observer, vol. iv.; Cave's Hist. Liter. vol. i. (q.)

IRKUTZK is a Russian Government in Asia, partly continental, partly insular, including the whole eastern part of Siberia. The former is bounded on the north by the Bay Sea, on the east by the North Pacific Ocean, on the south by the River Amur and Chinese Tartary, on the west by the Governments of Tomsk, Tobolsk, and Kolbyvane. The latter includes all the islands between Cape Lopatka, the southern point of Kamtschatka, and Cape Alaska on the shore of America; and to the north, all the lands hitherto discovered in the Frozen Ocean. It stretches between 2500 and 3000 miles in a straight line from the confines of Tobolsk to East Cape, and is the most extensive of all the governments belonging to this vast empire.

No country of equal magnitude, seems to present less diversity of climate. Extreme cold and continued snows prevail; the Northern Sea has obtained the name of the Frozen Ocean, from being navigable only for a short distance from the coast; and its islands are attained with greater facility by journeys over the ice than in transport by shipping. In places about 20 degrees, or 1400 miles farther south, it is necessary in winter to breathe through a handkerchief on leaving an apartment; while a misty atmosphere, consisting of hoar frost, forms around the body. The northern lights are constant and brilliant; they seem close at hand; they may be heard to shoot along, and assume an amazing variety of aspects, while the savage inhabitants of the country believe them to be spirits contending in the air. But in summer, though the heats of the sun be short, they are of considerable intensity; and, notwithstanding the rigours of the climate, earthquakes are not uncommon in some places.

Irkutsk is watered by many great rivers, of which River Lena is the largest, in general discharged into the Frozen Sea. Of these, the principal are the Lena, rising within the government on the north, pursuing a course of no less than 3850 miles, through 1530 of which it is navigable; the Kolyma, which flows 1200 miles; and the tributary streams, the Alden, the two Annis, the Vitim, Oleinka, and Kireina. To the south-eastern coast are the Anadyr, and the earlier course of the Amur, which is received by the sea of Okhotsk, opposite to the island or peninsula of Saghalien. The lake Baikal is likewise within the precincts of this government, and there are many medicinal springs.

A great portion of the surface is occupied by vast ranges of mountains, sending out their subordinate branches in every direction. Some of the principal lines terminate on the eastern shores, and seem to rear their summits again in the Aleutian islands, until they reach the American continent. The chief portions of the

* The first book only is preserved in the original Greek, and the rest exists in a Latin version of very barbarous style, through which, as well as from the subsequent reductions the venerable author is sufficiently apparent.
Alaskan chain proceed to the east and south. Many of the mountains are lofty and covered by snows; some have both active and extinct volcanoes. But almost all are imperfectly known, as Europeans have approached the bases of very few.

Mineralogy.

The views hitherto obtained of the mineralogy of Irkutzk are very general. Gold, silver, and lead, are procured in considerable abundance near Argunskoi, in the province of Nertschinsk; iron is got in different places, as also copper. The mountain Tchubekdelal, in the plains of Yakutzk, consists of iron-stone, free-stone, and strata of coal; six miles south-east of Argunskoi, there is a hill of beautiful green jasper; and on a hill by the side of the river Aldan, petrifactions of marine plants and shells are found at the distance of 333 miles from the nearest sea.

Botany.

Most of the plants seen in northern, and alpine countries grow here; but the climate is unfavourable for vegetation. At certain seasons those of an edible kind are carried 1100 miles up the river Lena to Yakutzk; and at Okhotzk the scarcity is such, that cattle are fed entirely on the offals of fish, and cows have been seen to prefer dried salmon to hay. Plants are low and stunted, but there are mountains covered with timber fit for ship building is plentiful, whence the Russians have travelled thousands of miles from their European possessions to reach some point of this government, where they could construct vessels for their voyages of discovery. Birch, poplar, ash, willow, and numerous plants producing berries are produced here, and also the larch, which ceases to vegetate in 68° 30' north latitude.

Probably the climate has been milder anciently, and thence more favourable to vegetable and animal life. The fossil remains of large quadrupeds, which are now totally extinct, and seem to have belonged to warmer regions, are now found on the shores of the Icy Sea, and in the deep banks of the rivers falling into it. Numerous living animals affording the finest furs, as the sable, ermine, sea otter, and squirrel, are dispersed in different parts. There are also the elk, rein deer, wild sheep, bear, lynx, wolf, and various kinds of foxes, besides the marmot and glutton. The most useful animals are horses and rein deer, herds of the latter quit the woods at particular seasons, and, descending into the plains, swim across broad rivers, having always a leader at their head.

The principal native tribes inhabiting the government of Irkutzk are the Tungoose, Yakutes, Koriaces, Kamutschadales, Tchutzkis, and Yukagiriaces. The Tungoose wander over an immense extent of country from the mouth of the river Amur to the lake Baikal, and from the Sea of Okhotzk to the Frozen Ocean. They are constantly in pursuit of wild animals, and seldom remain more than 20 days in the same spot, though their tents should be removed only a few yards. Mountainous regions are preferred by them, and they rarely visit such places as are frequented by the Yakutes. The latter, who call themselves Socha, are supposed to amount to 50,000 males. But in the year 1787 about 6000 of them migrated, with all their possessions, to the Chinese frontier. Formerly they possessed considerable wealth in horses and bufaloes; some are known to have had 20,000; no one, however, is now the owner of above 2000. The Tchutzki occupy the most eastern parts of Asia; they are divided into two tribes, the Stationary and Nomadic, though neither their numbers nor territory be great. The Yukagiriaces are reduced to an inconsiderable tribe, frequenting the sources of the Kovima and Yasasknoi in pursuit of wild animals; the Koriaces and Kamutschadales are also partly diminished, together with the islanders in the Northern Pacific Ocean. The islands in the Icy Sea, are all uninhabited east of Nova Zembla, which, if it is to be included in this government, only receives temporary visits from the neighbouring shores. All these tribes are idolatrous, they worship demons, and practice some singular ceremonies, which would deserve further detail. Attempts have been made to introduce Christianity among them, with very partial success. The whole, except the Tchutski, are tributary to the Russians, but although these have entered into alliance with them, they have hitherto denied their supremacy; and they opposed the only obstacle to the imperial dominions extending to that extremity of Asia. In a late work published at Moscow, the male inhabitants paying tribute, are stated to be 58,907 Buriatees, 14,480 Tungoose, 50,008 Yakutes, 505 Yukagiriaces, 40 Oiatorsians, 1221 Koriaces, 1782 Kamutschadales, 100 Kurilles, 545 Karagassians, a family of Sameoids. The total population is computed to amount to 407,758 souls.

This government is divided into four provinces—Ir- kutzk, Yakutzk, Okhotzk, and Nertschinsk. It contains two towns, several towns, a number of villages, and several fortresses. We believe, however, that the chief town of each of the provinces is called a city; and that the Russians, for the purpose of facilitating the administration of surrounding territories, are accustomed to confer that title on places which would be described as villages in the more populous and fertile states of Europe. Irkutzk, the capital, is situated on the right bank of the clear and rapid river Angara, which flows from the Lake Baikal, having the stream Ooshkafocka on the north and north-east. The streets are broad and in general uniform, but not paved, and the houses are for the most part built of wood. But their irregularity is great, and many miserable huts are seen amidst the finest edifices. There are, a cathedral, twelve churches, and two monasteries, all built of stone. A late traveller asserts that the churches amount to 30. There are various structures for the use of government; as an arsenal or dockyard, with the necessary buildings, called the admiralty, and a spacious customs-house. An infirmary was lately erected, and a workhouse for criminals. A gymnasia contains a library of several thousand volumes, and a collection of mineralogy, together with other subjects of natural history. The Japanese language was taught in it by command of the late empress of Russia. Irkutzk has a small theatre, wherein dramatic pieces are very tolerably represented by performers of both sexes, who are natives of the place. In the centre of the city there is an elegant square pile built of brick, with shops under piazzas, which support warehouses; the markets for provisions stand in a different quarter; and the slaughter houses are built over the Ooshkafoka. Provisions are plentiful and cheap; and as this city is the seat of considerable trade, an European may purchase here almost every article to which he has been accustomed in his native country; though Irkutzk is 4295 miles from the Russian metropolis, St. Petersburgh. Even the best foreign wines can be obtained at a very reasonable price. The merchants are numerous and affluent. Irkutzk is the general depot of all the furs which are brought from America and the eastern parts of Asia; and through it also is transported, all the merchandise sent from Russia to the empire of China, as well as to America by Okhotzki and Kamutschata. Here the furs are assembled, the best being sent to Moscow,
where they meet with ready purchasers. The second in quality, namely those of the sea and river otter, and other animals, together with the worst sables, and the fox skins from the Aleutian Islands, are allotted for China; for the Chinese prefer at a lower price inferior articles, as they colour and disguise them so artfully, that the deception can scarcely be detected. Belonging to the city, but at some distance, are a glass-house near the Lake Baikal; a distillery 40 miles north, and salt-works at three springs for supplying the neighbourhood.

The manners of the inhabitants of Irkutsk, though of European origin, are marked by many peculiarities, and participate deeply in those of eastern countries. An evident change is said to have taken place about the year 1790, or soon after. At that time there were neither inns nor coffee-houses in the city; yet, such was the hospitality of the inhabitants, that a stranger never was at a loss for a home. Merit was as great a recommendation as wealth; the higher ranks were distinguished by their liberality, and some individuals kept open house. About 17 or 18 years later, the greatest distrust is said to have prevailed among all ranks: females were never seen in social circles, and appeared only on public occasions; as at church, on festivals, at marriages, or balls. From the great extent of jurisdiction embraced by the government, and its being in the vicinity of the Chinese and Mongol territories, numbers of civil and military officers dwell in the city. Part of its inhabitants also consists of those exiles whom the cruel and reprehensible policy of Russia banishes from its own country, though their only crime may have been carrying arms in its defence. But they are left entirely at liberty; and some have acquired property by their industrious habits: the most skilful artizans and mechanics of every kind are to be found among them. It has been recently affirmed of this capital, that the inhabitants are not unhappy: that the climate is not so inhospitable as is in general believed; that the summer is pleasant; and that the surrounding districts produce a superabundance of corn, while those who wish for luxuries may obtain them at a reasonable rate. The population of Irkutsk is computed at 50,000. About 1739 miles north-east of this city stands Jakutsk, or Yakutsk, situated on the right bank of the Lena, a town consisting of 500 or 600 houses, 5 churches, and a convent. It is exposed to the inundations of the river, by one of which, in the year 1807, several of the inhabitants, and above 1000 cattle, were swept away. The streets are broad, irregular, and unpaved; all the houses are built after the old Russian fashion, and many are very spacious, with a court and garden. Bladder, or isinglass, is said to be substituted for panes in the windows during summer, and in winter plates of ice frozen into frames by means of snow. The situation of this town is less favourable than that of the former; the ground is never thawed above two feet deep, even in the heat of summer. We have already remarked the great distance which vegetables will be brought. Fish must be carried from places 266 miles off. In the month of June, every necessary of life is conveyed down the Lena, and at that time those who can afford it lay in a stock of provisions to serve twelve months. The town of Okhotsk occupies a sandy peninsular at the confluence of the rivers Okhotsk and Kuchatui on the coast of the Sea of Okhotsk. Inundations, combined with the rise of the tides during storms, gradually sweep away the beach; and so much damage was suffered in the year 1804, that the Russian government resolved to change the site of the town. It is a port, with docks, yards, and magazines. Thither the Asiatic tribes resort for the purpose of traffic, as they receive all the articles they require in exchange for furs. Caravans of 5000 or 8000 horses sometimes bring goods from Yakutsk for the use of the more distant Russian settlements. The town of Nertschinsk is of much smaller size than any of the preceding, and is situated on the immediate confines of Chinese Tartary. Here criminals from the other towns are condemned to work in the mines on account of government. There is a fortress at Nertschinsk, which is probably the strongest in the government, as many of the rest are falling to decay, from the decreasing eminence of the native tribes, once hostile to their invaders.

We do not know that the history of the government of Irkutsk can be traced to an earlier date than the middle of the 17th century. The Russians, penetrating by the west, progressively extended their conquests over the countries to the east for the sake of the fur of wild animals, until they arrived at boundaries claimed by the Chinese, where they expected to find silver mines. A sanguinary warfare was carried on between them in the course of the 17th century, which terminated in a treaty dated 1659. Prosecuting the discoveries of their hunters, the Russians advanced as the natives were subdued, or retreated. Taking another direction to the south-east, towards the close of the preceding century, they had engaged in hostility with Tchuteki tribes, who refused to acknowledge their authority, but who will probably find it difficult to preserve their own independence. (c.)

**IRON.**

Iron, in chemistry, is an elementary substance, and one of the metals. In the arts and manufactures, it may be considered as the most valuable of the metals. Its great importance in agriculture and domestic economy leads us to infer, that the civilization of man must have begun with its application to the various arts of life. Its tenacity has rendered it almost indispensable, for uniting and binding the parts of bodies made of wood and stone. Its hardness in the form of steel, has been of such importance in the various cutting instruments, that without it most of the useful, as well as the polite arts, would have been very little known to us. The great success with which it has been employed in the construction of swords and guns, is almost the only instance of its application we have to regret.

The first state in which it is necessarily presented to us when it is obtained from its ores, is in its combination with carbon, by which it is rendered hard and brittle. Under this form its most valuable properties are not observed: this is probably the state in which it was first known to man, and would be discovered perhaps as early as copper and brass. Gold and silver would be known much earlier; the first from its existence in the native form, and the latter in consequence of its easy reduction from its ores. Since malleable iron required to be formed from that called cast iron, and by a process
Iron.

Iron in the iron-stone loses its oxygen, and afterwards acquires as much carbon as the intended quality of the iron requires. After this is effected, the same furnace in another part, with the assistance of some foreign matter, must be capable of giving a greater heat than that required for the cementation, by which the earthy matter is separated, and the iron fused and collected in a recess at the bottom of the furnace. These different parts of the blast furnace we shall more particularly describe in the plans and sections represented in Plate CCCXI. Plate Figs. 1, 2, 3, 4, and 5, &c. A, Fig. 2, is the opening CCCXI, for the introduction of the materials. B the body of the furnace, where the cementing process is carried on. C the place where the blast is introduced, and it is a little above this where the greatest heat is produced. At this point the earthy matter is separated from the iron, which earthy matter, uniting with the flux employed, is converted into a fusible cinder or scoria. The iron being now fused, sinks down into the recess, or trough D, while the liquid cinder floats upon the liquid iron, defending it from the action of the blast.

Preparation of iron ore. A certain quantity of coke is employed. Part of this is to generate the heat necessary to its reduction, and another portion combines with the oxygen of the ore, and is deposited in the form of carbonic oxide. Besides this, a third portion combines with reduced oxide, converting it into a carburetted iron, which afterwards is cast into pig iron. The proportions of coke to the iron ore, or iron stone, is more or less dependent upon the quality of the iron to be formed; the richest and most highly carburised iron, commonly called No. 1, requiring the greatest proportion of coal, while the inferior iron, such as is known by the name of forge pig, requires the least coal. The greater the proportion of the ore to the coal, the greater is said to be the burden of the furnace.

The proportion of the fluxing matter to the ore, is in general determined by a number of trials with the blast furnace itself; yet it must be allowed to be a very expensive and unscientific method of proceeding.

There have, however, many facts relating to the fusibility of compound earths, and if such facts were yet to make out, a few experiments on a small scale would be sufficient for their accomplishment. This being ascertained prior to the commencement of an iron work, it would next be necessary to make a perfect analysis of the ore and the coal, with a view to determine the proportions of their earthy matter, the proportions of the ore to the coke being previously known. The fluxing material now to be added to these, must be such as to make the most fusible compound with the earthy matter in the coke and ore. This knowledge will enable the iron master to commence his work with the greatest chance of success, and the least risk of unnecessary expense, which is very considerable on the large scale of a blast furnace.
The preliminary experiments above mentioned, should always be made previous to any change in the coal or the iron ore, as the earthy matter in the former is very different in different beds, and sometimes even in different parts of the same bed. The argillaceous iron stone also varies in the proportion of its clay, and sometimes contains a considerable portion of silice, which, when it bears a certain proportion to the clay and lime, is easily separated. The iron stone abounding with shells, frequently contains carbonate of lime, and will require less lime to be added as a flux.

Formerly, the fuel employed in blast furnaces was charcoal, which is still used on the continent. The iron works, however, with a few exceptions, are carried on with the coke of pit coal, which is found to be much better fitted for making cast iron.

The coke is prepared, by piling heaps of coal on the ground in the open air. In some works, a short brick chimney is placed in the middle of the piles, which, having holes round the bottom, has the effect of inducing a current of air through the mass of coals on fire, and bringing them sooner into a state of combustion. In any part of the pile where the combustion is too rapid, a quantity of ashes are thrown from time to time, without which the carbonaceous part of the coal would become destroyed. Indeed, the operation of coking is intended to dissipate the volatile part merely. As this change is effected, the finished part is covered with ashes, and ultimately the whole combustion is stopped. The covering is to be kept upon them, till they are cooled below ignition. This coke, when cold and separated from the dust, is in the state to be used in the furnace.

The preparation of the iron stone is the next process, which consists in roasting it, for the purpose of separating its volatile matter. For this purpose, the stone is stratified with small coal, in a manner similar to that used in burning lime. These alternate strata are generally exposed to the open air, and the mass allowed to burn till all the fuel is exhausted. In some iron works, kilns, similar to the lime kilns, have been employed for this purpose.

During this process, camphor, carbonic acid, and water are separated. The stone assumes a reddish purple color, and consists of the pure oxide of iron and earthy matter, principally clay. The limestone, which is employed as the flux, requires no preparation except being broken into pieces.

In the practical management of a blast furnace, the coke is in general made a constant quantity, the proportions of ore and limestone varying with the quality of iron to be made, the season of the year, and the working order of the furnace. The proportions of the ore to the limestone, will be pretty nearly the same at all times when the ore is the same. To give the precise proportions of each would not apply generally, and can merely answer for the iron work from which our statement has been taken. The ore is argillaceous, and contains on the average about 27 per cent. of iron.

The limestone is that abounding with shells, from Critch, in Derbyshire. The coal is rather soft, but not very bituminous, and contains a large proportion of carbon. The furnace is that described under this article, which, at its common rate of working, makes about 40 tons of pig iron weekly. The blowing cylinder is discharged 25 times in a minute, and contains about 100 cubic feet. Hence the air discharged in that time is 2,500 cubic feet. The diameter of the nose-pipe is generally 2 inches.

At this, and most other blast furnaces, the metal is run out twice in the 24 hours, at intervals of 12 hours each. The latter periods are called shifts, from the workmen being changed, as the furnace is attended night and day. During the 12 hours, 50 charges of coke are used, at regular intervals, each charge weighing 24 cwt. During the same period, about the same quantity of calcined ore is added, at similar intervals. These proportions are the common melting iron, called No. 2. For No. 3, which has less carbon, this is called forge pig, the coke to the calcined ore is about 6 to 7. That of the best quality, called No. 1, and which contains the most carbon, requires less ore to the coke than No. 2. The limestone is also added at stated intervals; the whole quantity in the 12 hours being in proportion to the coke, as 4 to 11.

These proportions cannot be applied generally, so much depends on the nature of the materials, and other circumstances; some furnaces work to such a disadvantage, as to consume a quantity of coke equal to that above stated, and yet will not admit of more ore than will produce from 12 to 20 tons of iron weekly. Some of the Welsh furnaces, on the contrary, will carry so much burden, that they will bear the use of so much ore, as to give from 60 to 75 tons weekly. These great differences are dependent upon so many circumstances, as frequently to baffle the skill of the most experienced iron masters. Experience and strict observation are very essential points in iron-making; but science, mechanical as well as chemical, much facilitates the progress of this useful branch of manufacture.

We have before attended to these stages of the process, between the entrance of the materials into the furnace, and the discharge of the iron at the tap hole at the bottom.

The blast which enters at the point C, in Figures 1 Plate and 2, produces the greatest heat a little above this point, where the iron and the cinder are melted, and where the former drops into the cavity D. The oxygen of the atmosphere, in making its way through the combustible matter, soon combines with it, so that none, or very little, escapes from E to A. This part of the furnace, which we have called the cementing part, contains the ore and coke mixed together, and these will be affected just as they would be in a close vessel, that is, the oxygen of the air combines with the carbon of the coke, forming carbonic acid, or rather, carbonic oxide, which is generally the case at this single temperature. This change will go on, in each of the masses of ore, to the very centre, when it consists of metallic iron and earthy matter only. As soon as the oxygen is separated from the iron, the combination of carbon with the metal commences, and continues till, from the reduction of the mass below, it is in its turn brought to the melting point, when the lime combines with the earthy part of the ore, and the liquid metal falls down. The vitreous cinder, thus separated, also becomes iron, and being specifically lighter than the liquid iron, floats on its surface.

The melted iron occupies the part D, Fig. 1 and 2, in the furnace, and the cinder floats above it, till it runs off over the part d, which is called the dam stone. As the metal accumulates, the cinder is raised, and runs over the dam stone; and the metal itself ultimately would run over the same; but, previous to this, it is let out at the tap hole v, Fig. 5, which is on a level Fig. 5, with the bottom of the cavity which contains it.

The quality of the metal, with respect to its quantity of carbon, will depend upon the quantity and quality
of the coke, with which the ore has been surrounded in the cementing part. The appearance of the metal, when it flows from the furnace, will indicate when the coke has been in excess. A substance floats upon the surface of the metal, which, when cold, has a shining appearance resembling plumbago, and is known to the workmen by the name of *kish*. The presence of this substance shows that the metal is saturated with carbon; since it is found to consist principally of carbonaceous matter. If it is produced in any considerable quantity, it gives the iron master a hint to increase the burden of his furnace, by increasing the proportion of coke.

The appearance of the cinder is, also, a good criterion for showing the working order of the furnace, as well as the quality of the iron. When the ore is not sufficiently cemented, uncharred oxide, in some cases, and the defect of carbon, allows a considerable quantity of the oxide of iron to incorporate with the cinder; by which it assumes a greenish-yellow colour, which is not so favourable an appearance as the blue tint, or when it has the least colour.

In some instances, when the furnace is in very bad condition, the cinder becomes of so dark a green, as to appear almost black; this arises from a great excess of oxide of iron, which has escaped reduction in the furnace. This cinder is very flaky, from the presence of the oxide, and is considered a very unfavourable appearance. The cinder which has the least colour, soon becomes solid after it flows from the furnace, from its containing less of the oxide of iron. This shows that the cementing process is carried on to a proper extent, by which the oxide has been converted into carburetted iron, in which state it no longer can combine with the earthy matter, and desert it when the cemented masses are melted by the action of the blast. The blue tint in the cinder, which, in some instances, is almost as vivid as ultramarine, generally accompanies the more colourless cinder, and owes its colour, in all probability, to an oxide of iron, containing less oxygen than the black oxide. This may throw some light upon the mystery of the black and red oxide of iron being combined with quantities of oxygen, which are as 2 to 3, indicating the existence of a third oxide, which, in all probability, is that to which the cinder owes its blue colour. This idea is strengthened by the fact, that it is never produced but when there is the least oxide of iron in the rest of the cinder. Much light may be thrown on the subject of iron smelting, by a series of experiments upon the relative probability of different proportions of the earths. Previous to such a course of experiments, however, it might be advisable to make a correct analysis of the best cinder, which is that freest from colour, and at the same time fusing with the least heat.

We have generally stated, that the furnace above described, is supplied with 25,000 cubic feet of air in one minute. This fact is obtained from the area of the blowing cylinder being 12.56 feet, and the capacity 100 cubic feet, which being discharged 25 times in one minute, gives 2500 cubic feet in the same time. The steam cylinder is 32 inches in diameter, and the piston moves through 200 feet in one minute, working, it is stated, with 10 lbs. upon an inch. Then by multiplying 10, the pounds upon an inch of the steam cylinder, by 5.585, the area of the same, and dividing the product by 12.56, the area of the blowing cylinder, we get 4.44 lb. for the force of the blast upon a square inch, which is about the average in practice, as shown by a measured gauge attached to the blowing machine. This pressure would give a velocity equal to 635 feet per second.

If, however, 2500 cubic feet of air be discharged through a circular aperture of 2\(\frac{3}{4}\) inches in diameter, in one minute, this would give a velocity equal to 1073 feet per second. This indicates a loss of air at the waste valve equal to 23 cubic feet at each stroke of the engine. If no air were forced out by the waste valve, and 2500 cubic feet had to be expelled in one minute through the above aperture, the pressure of the blast would require to be equal to 21 lb. upon a square inch, and the area of the steam cylinder more than 17 feet, and its diameter about 4 feet 8 inches. If the present nose-pipe be used, and the blowing cylinder discharged 25 times in a minute, the area of the latter, suppose the piston still to move at the same rate, will be 7.25 feet, its diameter being a little more than 3 feet. If the steam cylinder, the blowing cylinder, and the speed and pressure remain the same; then, to prevent any escape at the waste valve, the diameter of the nose-pipe must be a little less than 3\(\frac{1}{4}\) inches instead of 2\(\frac{3}{4}\), its present diameter. In order to estimate the quantity of air which is blown into a furnace, it would be incorrect to take that which enters the blowing cylinder, as it will be frequently much less. Hence the quantity should be estimated by the velocity and the area of the nose-pipe, the velocity being first determined by experiment, by observing the pressure upon a column of mercury, since the velocity of air is as the square root of the pressure.

Let \(V\) be the velocity of air into a vacuum, with the pressure \(P\), which may be deemed 15 pounds upon a square inch.

Let \(p\) be any additional pressure, and \(v\) its velocity.

Then, since \(P+p\) acts against \(P\) when the air is discharged into the atmosphere, we shall have \(p\) for the moving force. Hence, from the above fact we have

\[
\frac{p}{P+p} = \frac{v^2}{V^2} \quad v = V\sqrt{\frac{P}{P+p}} \quad \text{and} \quad p = P\frac{v^2}{V^2 - v^2}.
\]

Let \(A\) be the area of the steam cylinder.

\(S\) be the pressure of steam upon a square inch.

\(a\) be the area of the blowing cylinder.

\(p\) be the pressure of the air upon a square inch, the same as the above.

\(b\) be the space the pistons pass through in 1 second.

\(v\) be the velocity of the air's discharge through the nose-pipe.

\(n\) be the area of the nose-pipe.

Then \(ap = SA\),

\[p = \frac{SA}{a},\]

Then from the above theorem

\[v = V\sqrt{\frac{P}{P+p}} = V\sqrt{\frac{SA}{P+ap}} = V\sqrt{\frac{SA}{P+P}}\]

also when no air escapes at the waste valve.

The value of \(v\) may also be obtained from the following operation, \(n = al\) and \(v = \frac{al}{n}\), but in this case no air must escape at the waste valve, it will then be more safe to get it from the theorem first given, in which \(p\) is obtained by experiment, or by the following equation, \(p = \frac{SA}{a}\). From these two equations all theorems may be obtained for calculating the diffe-
In the first \( a = \frac{n v}{l} \), and in the second \( a = \frac{SA}{p} \).

Hence \( \frac{v}{l} = \frac{SA}{p} \).

\[
\begin{align*}
ASl & = pvn. \\
1st, A & = \frac{p v n}{l}. \\
2d, S & = \frac{p v n}{A l}. \\
3d, f & = \frac{p v n}{AS} = \frac{v n}{a}. \\
4th, p & = \frac{ASl}{\frac{vn}{a}} = \frac{AS}{a}. \\
5th, n & = \frac{ASl}{p} = a l. \\
6th, v & = \frac{ASl}{\frac{pn}{n}} = a l. \\
7th, a & = \frac{n v}{\frac{SA}{l}} = \frac{SA}{p}. 
\end{align*}
\]

This contrivance was for some time considered an important discovery, but unfortunately another circumstance has also rendered it very objectionable. A quantity of water is carried into the furnace, as well in the state of vapour as mechanically, the latter arising from the spray produced by the agitation. This water has been found to have an effect upon the furnace, affecting both the quantity and quality of the iron; and has in many instances been abandoned, to re-adopt the old regulations.

Another means has been employed to equalize the blast, by what is called an air-vault. This consisted in blowing the air into a very large cavity. The experiment was first tried at the Clyde iron-works, by excavating a large cavity in a rock, into which the air was forced by the blowing machine. This capacity bore so great a ratio to the blowing cylinder, that the blast out of it was nearly uniform. This trial was not attended with success, partly from the vault not being air tight, and partly from the moisture which exuded from the rock mixing with the air.

A more successful experiment was made at the Carron iron works. An air-vault of wrought iron plate has been employed in one of the furnaces at Bradley in Staffordshire, which appears to answer very well. Its form is a cylinder about 10 or 12 feet diameter, and 50 or 60 feet long. Since the object of blowing air into the furnace is to produce heat, the heat being as the quantity; therefore the quantity which enters in a given time, will be as the velocity and the density jointly. If, however, the density of the air depends upon the compression, the propelling force will be increased, and the air is drawn into the furnace with too great a velocity. The cementing portion of the furnace is less perfect from the oxygen being carried too high up before it combines with the carbon, and the materials would be apt to disunite before the proper change is produced.

Hence it will be evident, that when the density is caused by its being introduced at a lower temperature, the velocity remaining the same, and such as is found to be free from the objection above stated, the effect of such a blast must be calculated to produce the best iron, and the greatest quantity of it. This, in a great measure, explains the fact of more iron, and of better quality, being made in winter than in summer. The same difference is not less conspicuous in all fires, which always burn most vigorously in cold weather. Hence it will appear, that in blowing apparatus, all causes likely to increase the temperature of the air should be avoided, and every artificial means of cooling the air should be employed, particularly in the summer.

In the common blowing apparatus, in which the air is compressed by a close wadded piston, a great heat is produced in the operation. This is partly produced by the condensation of the air, and some heat must result from the friction of the piston. In some experiments made by Mr. David Mushet, it appears that when the outer air was from 63° to 68°, the air immediately after its escape from the blowing cylinder into a receiving vessel, was increased from 63° to 90°, and from 63° to 99°. In an average of 30 experiments, the air in the act of condensing was raised 30°. This would have the effect of increasing its volume not less than \( \frac{1}{3} \) of the whole, and the increased pressure of the blast by this
can cause alone, would be nearly \( \frac{1}{4} \) lb upon an inch. Or, in other words, if the air were introduced into the furnace at 60\(^\circ\), the same quantity would be admitted with \( \frac{1}{4} \) lb less pressure upon an inch than if it were 90\(^\circ\).

Hence any means of cooling the air after its condensation, in all seasons of the year, must be attended with beneficial consequences. Iron, air, and its surface constantly kept wet, the evaporation from so great a surface, if freely exposed on all sides to the air, would cool the air very considerably. Indeed, without the aid of the moisture, the effect would be such as to recommend its adoption. In the summer season there would be some advantage in bringing the air under ground for a considerable distance before it enters the blowing machine; the reason for this will be obvious, from the earth being colder than the air. In the winter season, when the earth is warmer than the air, the supply should be from the atmosphere.

The increased temperature of the atmosphere in the summer, is the cause of another evil besides the increased volume of the air. The moisture necessarily accompanying it, is found to have a bad effect upon the furnace, which has been more especially ascertained by the use of the water-regulator, before alluded to. The quantity of water in the atmosphere at any time, depends upon the temperature, and the quantity of moisture prevailing on the earth's surface; so that the temperature does not always indicate the quantity of moisture which exists with the air. The most infallible method of finding the quantity of water in a cubic foot of space, is by taking the dew point, or that point of temperature when dew ceases to form upon the surface of a body which has been allowed to remain exposed in it for that purpose. The temperature of this body, for instance a bottle of cold water, will be the dew point. When a given space is saturated with moisture, at 70\(^\circ\), every cubic foot contains 4.53 grains of water; and the same space, at 50\(^\circ\), contains 2.96 grains. Hence, if the air at 70\(^\circ\) could, by passing through a culvert in the earth, be reduced from 70\(^\circ\) to 50\(^\circ\), 2.17 grains of water would be deposited from each cubic foot of air. This advantage, added to that arising from its diminished volume above mentioned, will, in a great measure, explain the difference in the quantity of iron made in winter and summer.

We shall conclude this department of iron manufacture, by a more particular reference to the plate exhibiting the different parts of the blast furnace.

Plate CCCXL. Fig. 1. is a section of the blast furnace, showing the interior of the furnace from the top to the bottom, and the part where the blast is introduced. The dark stripes which appear on the walls, are vent flues for the escape of moisture, which would not get off from such a massive building without injuring the walls, when the heat is applied to the interior. Fig. 3. is a plan at the level a a, Fig. 1. and 2, and Fig. 1. a plan at the part to which it joins. The light-colored squares are pillars of brick, constituting a false bottom, on which the hearth rests, the cavities underneath being for the escape of vapour, at the apertures w w in Figs. 4. and 5. Figure 4. is a plan across the aperture where the blast is introduced, in which the blast-pipes are seen. Although we have not before alluded to two pipes, we now observe, that it is only sometimes resorted to, the single pipe being much more common. Fig. 2. is a section elevation, at right angles to the former one, Fig. 1. showing the same interior surface and the dam-stone d, over which the cinder flows, while the metal is retained by the dam, till it is let out at a hole e, on a level with the bottom of the recess. t is called the tymph-stones, and forms a bridge over the cavity in which the liquid cinder rises. t is the tymph-plate, to give the stone greater firmness, as e is the dam-stone, which is called the dam-plate. See the tymph plate and dam plate, more particularly Figs. 6. 7. and 8. Fig. 5. is a plan at the bottom of the recess D, showing the vent flues in the piers, and the hole a for the outlet of the metal, seen also in the dam-stone, Figs. 9. 10. and 11. Fig. 11. is a side view of the large crow, in which the blast-pipe is inserted. The end of this iron is defended, from the immediate action of the fire, by covering it from time to time with stiff fire clay. Fig. 15. an end view of the same. Figs. 12. 13. 14. are different nose-pipes to fit the blast pipe.

Manufacture of Bar Iron.

All the varieties of pig-iron contain more or less of carbon, to which they owe their fusibility, which, in all the varieties yet made, are fusible in proportion to the quantity of carbon which they contain. In the earlier stages of pig-iron manufacture, an opinion prevailed that some varieties contained oxygen. Nothing could be more absurd than this idea. Experience has shown, that all varieties contain carbon, else they would not be fusible. And it will appear to any one acquainted with the laws of affinity, that carbon and oxygen are incompatible in a mass of liquid matter, as they must unite, and form an elastic fluid, till one or the other would be exhausted. It is this kind of pig-iron, containing the least carbon, which has been called oxygenated, and also forge-pig, because it has been found the best fitted for making bar or forge iron. It had long been suspected, that malleable iron was no other than the pig-iron diestved of its carbon, but the idea was not fully confirmed, till malleable iron was directly formed by cementing the carburet, or pig iron, with a substance which carried off its carbon without changing its form. This can be effected in small castings of pig-iron by the following process: Stratify alternately in a crucible the cast metal articles with powdered iron-stone (which contains an oxide of iron) in a close vessel, and let the vessel be covered by a lid very nearly air tight. Expose the whole to a strong red heat for ten or twelve hours, proportionate to the thickness of the castings. When the mass is cold, take out the pieces. If the change is complete, the pieces will bend and work with the hammer when hot, possessing all the properties of malleable iron. If, instead of the castings, some cast iron borings be stratified with small masses of the Cumberland iron ore, about the size of small peas, and treated like the last, the bits of ore will be found to be malleable.

In both experiments, the oxygen of the oxide combines with the carbon of the carburet, which escapes in the form of carbnatic oxide gas, leaving, if the oxygen and carbon be in proper proportions, pure iron behind.

Although this process appears the most direct and simple way of converting pig into malleable iron, the process at present employed is essentially different, and attended with very considerable waste. The method used by the ancients was still less scientific, and is still practised on the continent. It consists in laying the pigs of iron upon a hearth similar to a smith's forge, surrounding them with charcoal, and blowing the fire with bellows. The metal first melts, and is continually agitated with a rake, while it is exposed to the blast.
The carbon becomes gradually dissipated at the expense of the oxygen, which is afforded by the blast, and its fusibility is gradually diminished. It then becomes pulpy, and ultimately is obtained in rude shapeless lumps. In this state they are taken with tongs from the fire and placed under a large hammer, which is raised by machinery, called a stamping hammer. The anvil is broad, and is surrounded with tray-like sides, to keep the small fragments from falling off, which are apt to fly in all directions by the action of the hammer. The workman, with a rake, continues to push the pieces under the hammer so long as they keep their heat. These flattened and shapeless masses are called stampings. These pieces are then piled upon round pieces of fire-stone slabs, and placed in a reverberatory furnace, called a boiling furnace, and heated to a full welding heat. These balls are then placed under a forge-hammer, where they are drawn into bars about three inches square, and cut into lengths of half a yard in length. These pieces are called blooms. Each of these are heated a second time, and drawn by the forge-hammer into bars for sale. This is the old method of working, and is still practised by some, who have an idea that the iron is of better quality. It is attended with great waste, and, in the principal iron districts, is superseded by the puddling process, which we shall next describe.

The process of converting pig-iron into the malleable state, by the puddling method, is commenced by the operation called refining, which is performed in a furnace called a refining, and by some a run-out, furnace: this is represented in Plate CCCXL, and Figs. 16. and 17. The recess, or trough A, is made of cast metal, the bottom consisting of fire-stone or brick. It is surround- ed on three sides by a cavity, through which water is constantly passing from the cistern C. p p are two pipes from a blowing machine, inserted into the conical openings, and kept cool by water from the pipe a, which runs off at the pipe a. These are to blow the fire which occupies the recess A. The fire being made in the trough, and filled with cokes, the pigs of iron are thrown into the midst of it, and cokes heaped up around them, the blast being kept up, and the outsides of the trough being kept cool by the water. The metal first melts, and the blast, instantly acting upon it, separates a quantity of its carbon, but not nearly to the extent to which it is carried in the old method already described, as the metal still remains liquid. In this state it receives the action of the blast for three or four hours. It is then run out at the bottom of the trough through an opening e, temporarily stopped with sand. The melted mass is received into the shallow recess DE. A large quantity of the vitreous oxide of iron also runs on, which is formed by the blast, and floats on the surface of the melted metal. Indeed, it is through the medium of this vitreous oxide that the metal below is deprived of its carbon. The blast first destroys a portion of carbon on the surface, and then oxidizes the iron thus deprived of its carbon. This forms the vitreous oxide which floats upon the carbonated mass. The oxygen, therefore, of the floating oxide is constantly in contact with the carbon of the metal below. The stratum immediately below gives its carbon to that deprived of its carbon above, and thus the change is effected to the bottom of the trough.

The cake of metal, as run out, is then broken into pieces. Its fracture is white, and apparently crystalized, very different from its original fracture. This arise from its loss of carbon. These pieces are now introduced into the puddling furnace, which is represented in Plate CCCXL. Figs. 18. and 19. A is the ash pit; G the grate; D the door for the fuel; C the hollow cavity where the prepared metal is laid. The flame passes over it, and then up the chimney E; Figs. 18, 19. It is a door for the introduction of the pieces of metal. It is a cast-iron shell lined with fire-brick. In the bottom of this door is a square hole A for the introduction of the rake, and other tools used for working the metal. The workman, at the same time, can see the mass exposed, during the process, through the same aperture. Without this door the intense heat would prevent him from approaching the work, for the purpose of agitating it. Even with this guard against the heat, it is almost too great to be borne without great inconvenience. As soon as the metal is melted, the puddler begins to rake it about, occasionally throwing water upon it with a small iron dish. This water is decomposed by the iron and carbon; the hydrogen escaping, and the oxygen uniting with the iron, forming the vitreous oxide. This latter being condensed with the melted metal, continues to dissipate the remaining carbon. The fusibility of the mass gradually diminishes, till at length it loses all cohesion, and appears a loose granulated mass. During the time of this change bubbles of gas are seen to burst from the melted mass with a blue flame. This is the carbonic oxide. Soon after the metal has assumed the granular form, and the heat is raised, the fragments begin to adhere, and the whole forms a number of balls of an irregular shape. These consist of the iron deprived of its carbon, mixed with the vitreous oxide. These balls are made as compact as possible by beating them on the hollow hearth, with a very heavy iron rod shaped like a club. In this state they are brought out of the furnace with a pair of large tongs, and passed through rollers similar to those represented in Plate CCCXL. Figs. 20. and 22. first passing through the widest gates, and then in succession till the pieces become about three feet long, six or seven inches broad, and a little more than half an inch thick. In the finishing gate of the rollers, there is a protuberant part crossing the gate, which makes indentures across the bar, at intervals of about one foot each. This is for the purpose of breaking the bars into pieces of regular lengths when cold. It has, in this stage of the process, a certain degree of malleability while hot, but when cold is very brittle.

When the bars above mentioned are broken into lengths, they are laid one upon another five or six in depth, and are bound together with bands of rod-iron. They are now heated in a reverberatory furnace similar to the puddling furnace, but having a flat hearth. As soon as these bundles are heated to a full welding heat, they are separately brought out and passed again through the successive gates of the rollers. If the iron is not intended to be of the best quality, this rolling would finish the bars for sale; but if it is to be of a superior kind, the second rolling is carried only to the extent of the first, and the bars broken up into bundles a second time. Every time this is repeated, the quality of the iron is improved, as well as its tenacity, as being freer from specks, which consist of the small bits of vitreous oxide worked up with the iron. It has been observed by some, that, in the rolling process, where the hammer is not used, the iron is liable to abound with more vitreous oxide, which, when polished, is very conspicuous in small specks. It is believed that the hammer
Irrigation. Extensive use in the melioration of soils.

In very different latitudes and climates.

Plate CCLXZ. Fig. 21.

The second pair of rollers are different merely in the form of the gates. The angular gates are for rolling square bars. The bar is turned a quarter round every time it passes through one of these gates, so as to reverse the position of the angles. This is a second time; reversed, to take away the rhomboidal form of the bar which the first time through gives it. The first rollers, which the bars are passed through, are generally confined to that part only, having no other gates than what are required to form the bars, which are afterwards broken up to form the bundles for the second rolling.

When the iron is intended to be rolled into sheets, it is first formed into flat bars, and these are cut by large shears into lengths suitable to the breadth of the intended sheets. These pieces are transversely passed through plain rollers, differing from those described in nothing but the gates or grooves for the bars. Fig. 21 is an end-view of the rollers, shewing the iron shell on which the heated masses are laid before they pass through, and a similar one on the other side to receive the same. a a, are nuts working on screws to regulate the distance of the rollers from each other.

For the particular combination of iron with carbon, called steel, see Steel. For its chemical properties and respective combinations, see Chemistry. (c. s.)

Irregular douzeaves, in music, are all such tempered systems of twelve notes in the octave, as have more than two magnitudes of fifths in their scale, whose single resulting, bearing, or wolf fifth, does not fall between $\Phi G$ and $\Phi E$, which is the proper place of the wolf in regular douzeaves, which see. (c)

Irregular intervals are such, whose expression in Fenev's Notation (see that Article) lies or one of more of its justives $z$, $z$, or in larger number than the regular and progressive increase of them, which obtains throughout an arranged table of regular intervals, expressed in this notation. (c)

Irrigation. The improving of land by means of water, is an object of importance throughout the greater part of the globe. In various countries it is effected by nature on the great scale, occasionally or partially modified by human skill and labour. In others, nature applies this powerful mean of improvement in efforts more detached and confined. In some parts, irrigation, as a mode of improvement, is effected principally by the agency of man; and in all cases, this agency, skilfully applied, is more or less useful.

A just view of the fatal effects produced by destructive floods, compared with those which are the result of judicious irrigation, and of that sterility which is occasioned by excess or by want of water, compared with the fertile produce of lands properly irrigated, would set in a proper light the advantages resulting from this natural mode of improvement, by which water is turned to use, instead of being left to run to waste and ruin.

According to circumstances, it may be employed for meliorating soils of different characters, and for increasing the produce in many varied forms in most of the populous districts of the globe. The tropical rivers convey to the plains over which they flow, those annual and immense supplies of enriching deposit, which nourish the corn that sustains a considerable proportion of the population or they tend to form and to enrich those vast savannahs, which occur in that extensive portion of the earth. In the warm but more temperate climates, there are considerable tracts of soil, which, if not irrigated, are almost wholly barren; and water is also employed there, for the purpose of enriching soils already fertile. It is a cheap and powerful means for various crops of great value to man; and the use of it is extended, according to the views and circumstances of the husbandman, into the vineyard, the corn field, the garden, the orchard, or the meadow.

Instructed by nature, and improved by experience, in the use of this element for meliorating the soil, mankind has already felt that it is of great value and importance from the equator nearly to the 60th degree of north latitude, and from the same extending on a more limited scale partly into the southern temperate zone! The periodical rains within the tropics could not be sufficient in that burning climate, for nourishing the crops necessary to support the people, if nature itself had not employed them, and if art and labour were not also employed in fertilizing vast tracts of soil. Even in the milder climates of Italy and France, immense advantages are derived from this judicious application of this mode of improvement; and, though it may appear paradoxical, it is perhaps more productive still in the climate of England, notwithstanding its high northern latitude, and the moisture of its climate.

The truth is, that irrigation, when conducted on the right plan, is generally either proceeded or accompanied by draining, embanking, or both; and that it has therefore a tendency at one time to improve the soil and the climate also, while the element of water, instead of being destructive, is directed to purposes the most useful to mankind.

It is chiefly in this view, that a proper general idea may be formed of irrigation. The advantages of this mode of improvement are greatest in populous districts, where the produce of land is of superior value, and the labour necessarily bestowed on it may be had at an inferior price; but in all situations water is valuable, when it can be safely directed to enrich the soil, and to improve and augment the produce. Every one admires that beautiful arrangement of nature, under which putrescent substances, instead of being useless or noxious, become valuable, by affording new supplies of nutrition for living vegetables, and of course for animals; but water either is, or may become one of the most valuable means known for improving the soil in every climate, excepting that where the cold is long continued and severe.

Though much has been done in many parts of the globe, in order to attain the proper advantages to be derived from irrigation, it is probable that few of these in proportion have yet been secured. The rains which inundate the Nile, the Ganges, and other great rivers, do not convey the full benefits to the rich plains which they fertilize, unless by embankments the management and distribution of the water be secured, and the culture of the soil duly attended to. The deadly swamp, which is occasioned by water permitted to go to waste by stagnation, may be converted in many instances, by industry and skill, into fertile soil. Even the most barren mossy flats have often been converted into meadows by natural irrigation. But in how many instances is this neglected, where it might by art and labour be done? England furnishes the most alluring specimens of what is possible artificially, by means of wa-
Irrigation.

Irrigation and its conservative art and skill, re-convert perfecton.

The truth is, that if draining and embanking were conducted on liberal principles, with a view to, and in connection with irrigation, there would be far more advantage resulting from their union, than can ever be secured by attending to them separately. It may also be remarked, that these arts, though greatly improved, are yet far from practical perfection. Errors equally frequent and gross are still committed in them all, and these have a tendency to bring unmerited reproach upon arts of great utility to man.

It is not an easy matter to convince mankind, how much is really within the power of human skill and industry. The first settlers in the American colonies would not have believed what improvement, even in the climate, was to follow the draining and cultivation of their lands after the forests disappeared. Many ages elapsed, before the people of Egypt were capable of duly, appreciating the full swell of the Nile, and of turning its enriching floods to most advantage. The treatment and cultivation of soils enriched by flooding, and the due application of industry and skill in raising the most suitable crops, require time and patience; and can seldom or never be fully attained, unless the political state of a country be favourable to its improvement. In this view, irrigation fairly appears as a part of an extensive system of national economy, which ought to embrace the husbandry of every country to which this art can be of material use.

Irrigation. 315

Great efforts produced by human skill and labour.

Consequentces of irrigation in England.

Innumerable additional supplies of grass have been raised in England within the present age by means of irrigation. These have contributed in a very large proportion to the support of live stock; and of course they have added not only to the general produce and value of the soils on which this art was employed, but also to that stock of manure which has been turned, with great effect, to the purposes of arable husbandry. An increasing population has furnished at once the labour necessary, and markets for the produce; and irrigation has thus, indirectly, but in a very considerate degree, increased the value and the produce of corn lands. This known and important fact ought to recommend the continuance of a system fraught with so much advantage, and lead to further improvement in its principles and progress.

Attention and skill required in order to success.

Notwithstanding the generally enriching qualities of the floods which are sent down by tropical rains, it requires skill and attention to cultivate the soils to advantage, and to select in each case the most suitable crops. A cold and moist climate also requires a similar portion of skill in order to turn irrigation to most account; which answers in Britain much better for grass than for corn. Without this requisite skill and attention, it is evident that no art whatever can prosper: errors, therefore, which proceed from this want, ought in no degree to bring discredit on the art itself.

The art of irrigation, fully considered, and improved by observation, in connection with that of draining and of embanking, has been so highly improved in some parts of the globe, as to approach towards a scientific character. Its features vary, indeed, so much, in different climates, as hardly to permit us to view them in a proper light. We contemplate in succession, the new established system of irrigating for grass in England; that of the south of France and of Lombardy for grass, vines, olives, mulberries, and other purposes; and though much ingenuity and considerable diversity appear, we hesitate not to pronounce the whole included in one art. But where nature takes the lead, and human agency is employed only to promote the utility of her operations, we hardly recognize the art of irrigation: yet it is really of great importance, not only on the lesser, but the larger scale; and the shepherd who properly directs the course of a mountain streamlet, or turns the collected waters of his drains, in order to prevent stagnation or waste, and of course to promote the health of his flock, at the same time directing these waters in such a manner as to fertilize barren spots of soil, and thus to furnish additional supplies of food, really belongs to the same class of artists, as those who by means of embankment, or otherwise, direct to the most useful ends the vast inundations of tropical rivers.

The features of this art of irrigation appear very different, but the art itself is the same.

In what manner does water operate in fertilizing barren soils? As an element, it furnishes direct supplies of the food which is partly required for plants, as a medium for moderating the temperature of the climate, it lessens the rigour of cold in some regions, and of heat in others; as a destroyer of some noxious weeds, it extirpates, when under proper direction, many plants which are hurtful to agriculture, such as broom, heath, and moss; and it may be used in order to convey over the soil fertilizing and enriching substances. In each of these modes of operating there occur various features, and these must be well considered, in order to secure most of those beneficial effects which water is qualified to promote by irrigation.

It follows of course, that great attention ought to be given to the qualities of water intended for this pur- pose. There are various objects to be aimed at before the labour and expense in the application of it, these qualities ought first to be known. This may be done partly by analysis; but most certainly by experiment conducted on a moderate small scale. In general, spring waters are fertilizing, and possess also an equable temperature; but impregna- tions of iron are frequent and hurtful even in springs: petrifying springs, which hold lime in solution, are commonly fertilizing; mossy waters are generally poor; and such as convey enriching sediment, promise the most effectual and permanent improvement. These last, ought not, however, to be confined in basons, other- wise they will deposit their sediment there, instead of conveying it directly over the lands; but in particular cases, when these basons are to be occasionally cleared out, this caution may not be applicable and experience, to ascertain the fact; but there is no doubt
IRRIGATION.

that it may be ascertained with a considerable degree of assurance before expensive efforts are made.

The qualities of the water, and the natural produce which it nourishes most effectually, being discovered in the first place, it belongs to the farmer to consider the population and markets of the district, his own demands, and the nature and extent of the irrigated crops by which he may expect to derive most profit. A prudent man will be determined in a considerable degree by these considerations, before he embark deeply in the undertaking.

The water meadows of England present a fine view of irrigation for grass, a description of which belongs rather to other portions of this work, and will partly be found under the article AGRICULTURE, and in those works to which reference is there made. A similar account of French irrigation will be found under the article FRANCE of the present work; and that of Lombardy and other nations, will fall to be introduced under other heads.

In Scotland there have been many successful essays in irrigation on a lesser scale; but the greatest attempt was made by the late Duke of Buccleuch on his pastoral estate on the rivers Esk, Ewees, Tiviot, Etterick, and Yarrow. Neither the water nor the climate in general, were favourable to this liberal effort on the great scale on which it was made; and the wants and population of the district hardly warranted that scale; besides, it was conducted mostly in that mode which requires most water and most expense; and it was necessary for this purpose to sacrifice too much of those level soils which are most valuable for other purposes in that alpine part of Scotland. The art of irrigation is best promoted when success as well as failure are properly recorded: and the failure of this great attempt is particularly accounted for in the Farmer's Magazine, 1815, page 42, &c. But many good specimens of irrigation occurred under this attempt, some of which are still preserved; and many other successful efforts have been made by watering for improving the meadows in all quarters throughout Scotland, the climate and richer waters of England being, however, generally preferable.

There, in favourable circumstances, it is common to obtain by irrigation three successive crops, viz. two of pasture grass, and one of grass cut for hay or soiling, all in one year. This fact leads us to consider the climate in connection with soil, and water, and other circumstances; and in applying this art to the agriculture of many foreign parts, a similar advantage is obtained by nourishing various crops in the same year.

The resources which may yet be opened to many nations by means of irrigation, fully understood and practised, appear to exceed all present calculations; and what is already known of this art is amply sufficient to attract towards it the notice of the legislator as well as that of the husbandman. Water may be made to furnish a rich and extensive supply of manure to the soil, merely by giving it a proper direction, which will have the further good effects of preventing that waste and ruin which frequently accompany this element when it is left without any direction. Even the drainage of wet soils may thus be rendered valuable for the improvement of other lands, and what naturally tends to do harm may be turned to advantage.

It has become, in most of the cultivated parts of the globe, a serious and expensive matter to preserve the soils in full bearing by regular and frequent manuring. The cost of lime, dung, and other fertilizing substances, is considerable, and the carriage and application add materially to it; nor is it always in the farmer's power to apply his manures in the proper season, and to the requisite extent.

Irrigation supplies manure in favourable circumstances, at less expense, and with more effect, than almost any other mode, on the soils to which it is applied; and the produce of it on these furnishes increasing means for the manure of other soils. The limits of this improvement are not fixed; and an agriculturist who wishes to extend his farm may, while following the natural course of the land and rivers, so far as may be consistent with the object, add streams of water, where the natural topography will allow it, by proper embankments; and in this manner he may serve the purpose of irrigation, and yet avoid the expense and evils of various works in the different parts of the kingdom, which have been the subject of the preceding sections. But it is only prudent to undertake this operation gradually, as it is always best to follow the natural course of the land; and in this manner we may see many thousands of acres being improved at less expense, and with more effect, than any other mode, on the soils to which it is applied.
which is situated in the middle of the street. The harbour of Irvine, formed by the estuary of the river, is commodious, but will in a great degree be superseded by the new harbour at Troon. There is from nine to eleven feet of water on the bar at spring tides, which is increased to 16 feet in high storms, with a wind from the south or south-west. Several busses for the herring fishery formerly belonged to this port, but the coal trade is now the principal one, and is carried on by a number of hirigs, which export 24,000 tons of coals annually. The articles of import are iron, hemp, flax, wood, and grain. Besides the grain brought coastwise from Galloway, about 10,000 quarters have been imported in one year from Ireland. Its principal manufactures were those of carpets, muslins, silks, lawns, which were exported in considerable quantities. There is also at Irvine a dockyard for shipbuilding, a large tannery, a rope-yard, and a bleachfield. A public library was established in 1795.

It is not known at what time Irvine was erected into a royal burgh, but a charter from Alexander II. is extant, confirming the grants of other sovereigns. The magistrates have a good revenue arising from the customs, and from a large tract of land, which was rented at £500 per annum. In the town of Irvine are branches of the Old Paisley Bank and the Ayr Bank. Irvine is 15 miles east from the Isle of Arran, and 61 from Edinburgh.

The following is the population abstract of the town and parish for 1811:

ISCIA is an island of the Mediterranean, about 18 miles in circuit, situated at the eastern entrance of the Bay of Naples, which is supposed to have been produced from the sea by volcanic eruptions. This island is situated in an agreeable climate: the sky is seldom obscured by clouds; the summer is temperate, and the winter mild. Its aspect is greatly diversified, presenting a mountainous and irregular surface, in general, intersected and interspersed with some portions of fertile soil, under good cultivation, and abounding with grain and fruit; while other parts consist of nothing but dark and arid rocks, marked by sterility. Ischia, however, is principally interesting to the mineralogist, from the various volcanic products dispersed in every spot, both of the island and surrounding rocks. Lava, of the hornstone base, and tufa, are the component parts of the Castle Rock, somewhat exceeding a quarter of a mile in circuit. The same appearances are exhibited by a neighbouring mountain, from which this rock is divided by a narrow channel, which has probably been made by the action of the waves. Other mountains consist of similar substances, as the Irotaro, between Casamicciola and the city of Ischia, formed of tufa, pumice, and enamels, which last are found in no other place. Monte Zaro has been produced by a stream of lava, a mile in length and two in breadth, the consequence of successive eruptions. Its base, on one side, is washed by the sea, and covered by a vitreous sand, which under the microscope seems to consist of particles of feldspar; and towards the land there is a spacious tract, almost entirely tussocky, scattered with fragments of pumice. Besides the mountainous parts of the island, great rocks of lava protrude through the ground in different places. The various lavas are distinguished by colour and consistence, and by the proportion of feldspar, and other characteristics. In that of Monte Imperatore, feldspar seems to constitute its entire substance. At the Calce de Panza there are clusters of yellowish white species, some of it two inches long; and many hundreds are grouped together, into roundish masses of half a foot or even two feet thick, having the lower extremity in the lava. Independent of these volcanic substances, ferruginous sand is found in many parts of the island, and in particular abundance on the sea shore. This at first sight apparently consists of very minute, irregularly shaped iron particles; it with the aid of a powerful magnifier, each grain is discovered to be the fragment of a crystal, or a crystal complete; but of the latter there is not the proportion of above three or four in a hundred grains. These minute crystals are formed of two pyramids, united at the base; though for the most part they are only incomplete fragments, the defective parts having been destroyed by the action of the waves. Alum was formerly obtained for commercial purposes at Catrico, a place on the higher eminences of the Mount San Nicola; but some observers were subsequently unable to find any indications of it. The Abbé Spallanzani, however, collected numerous specimens of lava there, and in the environs. After remaining for some months in his cabinet at Pavia, those which had been affected by acids were wholly encrusted by a whitish thin coating of alum, others exhibited none; whence he concluded there are two species of lava, and that the fabrication of this salt might be profitably renewed in Ischia.

M. Dolomieu affirms, that notwithstanding the remote period when the last eruption took place, namely in 1802, the lava of a tract called Arso still smokes in many places. Later naturalists have been unable to confirm this observation, nor does he say that he himself witnessed the fact. Nevertheless aqueous vapours are constantly escaping from fissures in the lava, which are converted to medicinal purposes, under the name of stoves. The vapour is collected and conveyed by tubes into apartments, whereby a steam bath is obtained, and the patient brought within its sphere is covered by a fine, crisp perspiration. Many such baths are seen here, and known by different names, some of which are relative to the disorders in which they are believed to be most efficacious. About a mile south of the town there are wells impregnated with saline and sulphurous matter, which are also resorted to for various dispondemps.

Notwithstanding the volcanic origin of this island, many parts are extremely fertile, and numerous plants flourish luxuriantly upon it. Various fruits attain great perfection. The inhabitants have pleasant gardens; and the level grounds abound in groves, which, however, are said to be frequently cut down, perhaps from the shallowness of the soil.

Ischia, the capital of the island, is situated on an insulated rock on the north coast, and connected to it by means of a bridge and a subterraneous passage, which was wont to be closed by an iron gate. It has a castle and an hospital, which latter was erected by a benevolent society of Naples, and it is an episcopal see. Some hundreds of invalids repair from the neighbouring continent to the hospital during the bathing season; and in their conveyance and return, several barks are always employed. Those who are cured leave votive
ISL

It is offered to the Virgin Mary, or to tutelar saints. Many neat villages are distributed along the coast, and detached habitations are interspersed over the whole island, even at an elevation where vegetation almost entirely ceases. On the summit of San Niccola, a hermitage, consisting of a chapel and three cells, has been excavated from the volcanic rock, which are inhabited by three hermits. One of the hermits always traverses the island in quest of what is necessary for subsistence and the service of the altar, which is willingly bestowed by the inhabitants, who themselves perform an annual pilgrimage to the chapel. The island consists of three parishes, and contains a nunnery. It was formerly exempt from taxes, and the King of Naples was accustomed to come hither every year, on which occasion he allotted portions for indigent young females.

Ischia was called Onaria, Inarina, or Pythaca by the Greeks and Romans; according to some, from having abounded in monkeys; and according to others, with little probability, from circumstanes relative to Æneas. Strabo relates, that the first inhabitants were obliged to quit the island on account of its volcanic eruptions; and it remained deserted until 450 years before Christ. Hiero, King of Syracuse, fruitlessly endeavoured to settle a colony here; but one was established by the Romans, who retained it until the time of Augustus. A great eruption happened in the year 1302, by which many of the inhabitants and their cattle were destroyed. The survivors escaped to other islands, where they resided during the two months that it lasted. See Spallanzani’s Travels in the two Sicilies, vol. i. Pococke’s Travels, vol. ii. part 2. (C)

Isere is one of the eastern departments of France, and derives its name from the river Isere, with which it is traversed from east to west. It is bounded on the north by the department of the Ain; on the west, by the departments of the Rhone, the Loire, and the Drome; on the south, by the Drome and the Higher Alps; and on the east, by the departments of the Higher Alps and of Mont Blanc. The principal rivers are the Romanche, the Drc, and the Isere. It contains 453 square leagues, and contains four districts, 44 cantons, and 583 communes. This department is occupied principally by barren and marshy plains, deep valleys, and high mountains. Grain, hemp, wine, cheese, and pasture, are its principal productions. The woods of this department occupy about 270,000 acres. The forest called Chartreuse is remarkable for the beauty of its trees, owing to the serupulous economy of its ancient proprietors. It has mines of iron, copper, lead, coal, quarries and mineral waters. Its annual contributions were 5,546,889 francs, and its population 441,288. The principal towns are,

ISLAS Table is the name given by antiquaries to an Egyptian monument, in the form of a plate of copper or brass, containing various figures in bas-relief. This piece of antiquity was discovered at Rome in the year 1528, when the Constable Bourbon took that city. It was purchased from a soldier by a locksmith, who sold it to Cardinal Bembo, after whose death it came into the possession of the Duke of Mantua. When Mantua was taken by the Imperialists in 1530, it appears to have been lost, as it has never since been heard of. It was, however, engraved in its full size by Aeneas Vico of Parma. This plate was divided into three horizontal compartments, containing hieroglyphics and figures of gods. Antiquaries are not agreed respecting the object of this piece of antiquity, and there is some reason to believe that it was fabricated at Rome. See Banier’s Mythology, vol. i. p. 567; Jablonski, Pantheon Egyptianum; Pignorius, Characteres Egyptiani; and Jablonski, Miscellanea Berolinensia.

ISIS. See Masonry Free, and Mythology.

ISLANDSHIRE. See Durham.

Islay is the name of one of the Hebrides, or Western Islands of Scotland. Its form is irregular. Its greatest length, from the Mull of Oa on the south, to Rumhail on the north, is nearly 31 English miles; and its breadth, from the point of Ardmore on the east, to the farm of Sanaig on the west, is about 24 miles. Its superficial extent is nearly 164,000 acres, of which one-seventh is in occasional or regular tillage; two-sevenths are rugged mountains, rocks, or hills; three-sevenths hill pasture, coprice woods, plantations, and natural grassings impervious to the plough, and one-seventh unimproved, but improvable, moors, peat mooses, and unreclaimed wastes.

The island of Islay belongs to Argyllshire, is divided into three parishes, Killarow, Kilchoman, and Kildalton. Killarow, frequently called Bowmore, from the name of the village where the church is built, is about 18 miles long and 8 broad. It is watered by the river Laggan, which runs into a bay of the same name. Its population, including Kilmoy, was, in 1811, 4635. Kilchoman is about 20 miles long, and six broad, and is intersected by two arms of the sea. Lochgulinart and Lochindal. Its population in 1811, was 3151. Kildalton is about 15 miles long and 6 broad. About two square miles of the parish are covered with natural wood, from which all the island is supplied. Its population in 1811, was 269. Hence the population of Population Islay in 1811, was 10,035.

The coast of Islay is in general rugged, and is indented with numerous bays and harbours, the chief of which is at Lochindal, where there is also a quay opposite the village of Bowmore. Lochgulinart and Lochindal, two arms of the sea, seem to have been once united so as to divide Islay into two islands. The highest land between them is not more than 20 feet above high water mark, and the soil is a thin stratum of moss lying upon rounded selustus, mixed with great quantities of marine shells. Some of the mountains in the east and north of the island, are nearly 1300 feet high. The fresh water lakes, amounting to about 80 or 90. cover nearly 3060 acres. Lochgulin occupies about 700 acres. and Lochfinlagan, which is about three miles in circumference, has an islet of the same name in the middle, strongly fortified. Three or four streams, abounding in salmon, water the island.

In this island there are nearly 48 square miles of primitive limestone, without animal exuviae, but containing lead ore mixed with copper, which has been wrought with success. Manganese and coal have been found, and specimens of the finest iron ore were found in 1808. The copper ore, when richest, yields 33 pounds per hundred, and 40 ounces of silver are obtained from a ton of the metal. Veins of emery, from one to three feet thick, have been found on the top of a hill near Portascaig, and a small quantity of quicksilver has been found in the moors, and at the bottom of wells. Inexhaustible pits of hard and soft marl oc-
cur in Kilarrow and Kildalton, and great quantities of seaweed are thrown ashore for the purposes of kelp and manure.

Agriculture.
The principal crops in Islay are barley, oats, flax, potatoes, beans, peas; and even hemp, wheat and every species of green crop are grown. The cultivation of wheat was introduced by the late Mr. Campbell of Shawfield, and considerable quantities are now raised annually by several of the more opulent tenants. Several thousand bushels of potatoes, and considerable quantities of barley are exported annually. Nearly 3054 acres are occupied by the potato crops, upon which about 60,680 bolls are raised at an average. There are no more sheep kept in Islay than are necessary to supply the island with wool and mutton. It is necessary, indeed, to import considerable quantities of wool.

The principal wealth of the island consists of black cattle, of which the following numbers were exported from 1801 to 1807:

<table>

which gives an annual average of 2604, the value of which at £7 per head, will be £18,484. The best part of the saleable cattle are exported to Dumbarton, Falkirk, and the lowland markets. If we suppose the quantity of cattle exported to be only 4th, this will give 10,502 as the stock of Islay. The cattle exported are generally three-year-old bullocks, and yield heifers and cows. The number of cattle in the possession of gentlemen farmers in Islay is about 6795, the remainder, viz. 3767, belonging to the tenants and cottars. In 1810, the number of milk cows was 1357.

Islay also exports considerable numbers of horses. The Irish dealers buy the refuse of them, amounting from 120 to 180 annually, at from £7 to £12 each. The number annually exported, amounts to between 250 and 300.

Manufactures.
The principal articles of manufacture in Islay are linen yarn and kelp. Besides the quantities manufactured and used in the island, about £2000 worth of linen yarn has been exported annually during the years between 1797 and 1807. The manufacture and cultivation of flax was also encouraged by Mr. Campbell, who built flax mills for this purpose. As the extent of the coast of Islay is nearly 200 miles, it might have been expected that a great quantity of kelp would have been raised in the island. Owing, however, to the small height of the tides, and the rugged nature of the coast, only about 200 tons are manufactured annually. All the tenants were permitted to make kelp upon their farms, the proprietor restricting himself to the receipt of one third of the market price when it was sold.

A packet, which is a steep of 30 or 60 tons, sails from Portcharlock to Tarbert in Kintyre; for letters, newspapers, and passengers; and two regular packets trade at all seasons between Bowmore and Greenock. The fishermen often carry over to the coast of Ireland, cargoes of stenlock, which they sell under the name of wick salmon.

Villages.
The late Mr. Campbell built the two thriving villages of Bowmore and Portnahaven; and, by his liberal policy, many hundred acres round these villages, which were merely peat moors, are now regularly subdivided and enclosed, and covered with the finest crops. There is a market for horses at Bowmore, on the first week of August, which is chiefly frequented by Irish dealers. The population of Bowmore in 1808, was 305 males and 365 females, making in all 670. The number of scholars at the parish school was 124, who were taught Latin, English, arithmetic, book-keeping, navigation, &c. At Portnahaven, there are 26 families of fishermen.

About 40 years ago there was no carriage road, and Roads, only two or three carts on the whole island; but in 1808, there were 90 miles of carriage road in different directions, and above 500 carts.

The quadrupeds, according to Mr. Pennant, besides Animals the domestic animals, are weasels, otters, and dark-coloured hares. The birds are eagles, penguins, falcons, moor-fowl, ptarmigans, red-breasted goosanders, wild geese, ducks, herons, &c. and the fish are plaice, smears, dab, large dals, mullets, ballans, lump-fish, and sometimes the lepadoaster of M. Gouan.

From the dominion of the Danes and Norwegians, History, Islay came into the possession of the Lords of the Isles, who kept it till the reign of James III. When their powers were abolished, the Macdonalds, their descendants, became the proprietors of it. In consequence of an invasion of the island by the Macleans and Macleods, countenanced by James VI. Sir James Macdonald, the proprietor, was defeated. He escaped to Spain, and, having received a pardon, returned in 1628. The property of Islay was then transferred to Sir John Campbell, a great court favourite, on condition of his paying £500 per annum of feu-duty.

A great part of Islay, which was possessed from 1626 to 1717 by the family of Calder, was sold to Mr. Campbell of Shawfield in 1717 for £12,000, including a part of Jura; and in 1748, the late Mr. Campbell bought another part of the island for £10,000; so that deducting the sum which he received by selling the part of Jura, the purchase money of Islay may be stated at £15,000. The rents in 1779 were £2700, and in 1807 they exceeded £11,000. Mr. Campbell, the grandson of the late proprietor, possesses the whole island, excepting two farms, which belong to Mr. Campbell of Ballinany.

Huge trunks of oak, sycamore, and birch, are found in the peat moors, the remains no doubt of the "many woods" which, in 1540-1, Dean Macferson describes the island as possessing. See Macdonald's General View of the Agriculture of the Hebrides, Appendix, p. 612. Edin. 1811, to which we have been indebted for the principal information in this article.

ISLE OF FRANCE. See MAURITIUS.

ISLE OF WIGHT. See WIGHT.

ISINGTON. See MIDDLES.

ISMAIL, or ISMAILI, is a TOWN of European Turkey, in the province of Bessarabia. It is situated on the left bank of the Danube, and extends about half a mile along the river, and about a mile towards the land. It was fortified with eight bastions, the ramparts being from 18 to 25 feet in height, and the moat from 20 to 40 feet deep. Horizontal batteries and ramparts defended the site next the water, and near the town was a cavalier of stone work, capable of holding some thousand men. This town was taken by storm by the Russians under General Suvarow, on the 22d December 1799, after having experienced several checks, and lost 10,000 men. The Turkish garrison, amounting to 20,000, were massacred in cold blood; and the city given over to the unbridled licentiousness of the soldiers. No fewer than 250 pieces of cannon were taken, 345 standards, 10,000 horses, and a great deal of other booty, to the value of ten millions of piasters.

ISON, in Music, a term anciently used for the Key-note, or fundamental of a piece of music, called also the Musc.
ISOPERIMETRICAL PROBLEMS.

ISOPERIMETRICAL Problems are problems in the higher geometry, in which it is required to determine the nature of a curve, from some properties given which it is supposed to possess in a greater degree than any other curve, either drawn between given points, having an equal length or perimeter, comprising the same area, or under other similar restrictions.

The first proposal of such problems forms a remarkable epoch in mathematical history, on account of their presenting difficulties of a peculiar kind, to the surrounding which the ordinary application of the differential calculus in questions of maxima and minima was at first supposed inadequate, and demanding more extensive views than had before been taken of the variations which magnitudes undergo by a change in the manner of their composition; thus giving rise to a succession of profound researches, which terminated at length in the invention of the calculus of variations, one of the greatest discoveries in the modern analytics, and tending remotely to the establishment of the differential calculus itself on principles purely analytical.

The property of a straight line, by which it measures the least distance between two given points, is too obvious to escape the notice of the most ordinary observer. That of the circle, by which it includes the greatest area under a given circumference, is demonstrated by Pappus, in the 5th book of his Mathematical Collections, with the greatest precision, (Prop. 10.) and though his mode of proceeding, founded on the inscription of regular polygons, will not apply to the sphere, on account of the impossibility of inscribing regular solids within it to an indefinite extent, yet that figure seems to have been generally regarded as the most capacious under a given surface. The first instance, however, of a problem of this kind resolved by direct investigation, was furnished by Newton, in the construction of a solid of revolution, which, when moving in a fluid in the direction of its axis, shall be less resisted than any other of the same base and altitude. The demonstration, however, of the property by which he has characterized the figure in the 2d book of the Principia, (and which is merely its differential equation geometrically enunciated,) is suppressed, and no trace of the method by which it was obtained appears. Nor does it appear (at least immediately,) to have excited the curiosity of others, since, after a lapse of nine years, and upon another occasion, the attention of the mathematical world was first fixed upon the subject; and from that period researches of this nature assumed a regular and definite character, and the method of conducting them began to be distinctly seen.

No sooner had the newly acquired power of the differential calculus enabled John Bernoulli to resolve the problem of the catenary, which Galileo had in vain attempted, than another, proposed by the same philosopher, and whose true solution had in like manner eluded his penetration, offered a farther occasion of proving the force of the new methods. It was the problem of the Brachystochrone, or curve, down which a body will descend in the least possible time from one given point to another, in a vertical plane. This was evidently a question of far greater difficulty than any ordinary problem of maxima or minima. In the latter, the form of the function which is to become a maximum or minimum is given, or at least may be determined by proper considerations, independent of the maximum or minimum property, while, in the former, it is this very property which determines the nature of the curve in question, and by consequence, of the function to be made a minimum. It was not, however, by any direct analysis, setting out from this property as his datum, and following it as his directing principle, that Bernoulli first resolved his problem. The minimum property of his curve appears to have struck him as a collateral view, in the course of investigation of a widely different nature; and a succinct account of the course pursued by him, and the progress of his thoughts, may materially assist us in our inquiry into the early history of these problems, and, at the same time, serve to illustrate their nature.

It is well known that Fermat had early signalized himself by the discovery of a method of maxima and minima, which has procured him, and with reason, the reputation of having invented this application of the future differential calculus. Of the various results afforded by his method, the following was not the least remarkable; that, on the Huygenian hypothesis of the refraction of light, where its velocity before refraction is to that after, in the inverse proportion of the refractive densities of the media, its course is necessarily such, that in passing from a given point on one side of a refracting surface to one on the other, the time occupied is a minimum. This singular conclusion had, however, been anticipated upon a metaphysical principle, (if it deserve the name) that, as nature always operates in the most direct and simple way, therefore, by some necessity, the ray must shape its course so as to arrive at its destined object in the least time possible. The principle, at the instance of Clereselius, and the preponderance of natural good sense, was given up by Fermat, as soon as he had learned to regard the fact as a consequence rather than a cause of the laws of refraction; but Leibnitz and Huygens strongly adhered to it, the former defending it from his peculiar views of final causes, while John Bernoulli professed himself convinced by their arguments, so that, without farther consideration, it became a received principle, that, under all circumstances, light performs its course, however interrupted, from point to point, however distant, in the least time that circumstances will permit; and in this form it was laid down by Leibnitz, in the Act. Eruditorum, 1682, as the foundation of optical science, and attributed by him to the immediate fiat of the Deity.

Bernoulli had proposed to himself, to determine the path of a ray through a medium, whose refractive density (and consequently the velocity of the ray) varied according to a given law, in which investigation, no difficulty occurred. Having (from the pre-established dependence of the sine of refraction upon the refractive density, and without any consideration of the velocity,) ascertained the curve described, and satisfied with the metaphysical principle above stated, he then abstracted altogether from optical considerations, and regarding the variation of velocity as produced by any cause, as, for instance, the force of gravity, he thus concluded the brachystochrone on any hypothesis of gravitation.

It is surprising to observe what ascendancy these considerations of metaphysical propriety had, at that
period, obtained over the mind of this singular man. No sooner had he identified the brachistochrone, on the supposition of uniform gravity, with the cycloid, which had previously been identified with the tautochrone, on the same hypothesis, than he celebrated it as a wise dispensation of Providence, or, at least, as a wonderful instance of the frugality of nature in her operations, thus to make one curve serve two purposes; observing, that this could not have happened, were not Galileo's hypothesis of uniform gravity agreeable to nature, although Newton's discoveries had long ago demonstrated its falsehood, and Bernoulli well knew the fact to be so.

It would not be difficult to clear Bernoulli's solution from any objection on the score of rigour; and, in fact, he speedily obtained a more direct one, upon which, in June 1696, he proposed his problem in the Leipsic Acta, under the title, Problema novum, ad curvam solutionem Mathematicum invitantur, allowing six months for the solution, which, however, at the request of Leibnitz, who, as well as his brother James Bernoulli, had resolved the problem, was prolonged to a year. At the expiration of this period, a multitude of the chief mathematicians of the age were found to have been successful, but the only direct analysis which appeared was that of James Bernoulli. The principle on which this analysis turns is of very extensive application, and it once reduces this, and other problems of the same nature, to questions of ordinary maxima. It is this that the maximum or minimum property, which belongs to the whole curve, belongs also to every elementary, or infinitely small portion of it. It is true, this principle is not absolutely general, and therefore must be verified before it is applied in any particular case. In the present it is easily shown to hold good.

Let ABCDE be the curve (Fig. 1.) required, BCD will be the consecutive velocity with which the arc CD = d s + d' s (= d's') is described. Now, to discover what function y is of x, we must endeavour to establish some relation between the differentials d s and d y or d s, by means of the proposed minimum property; and to this effect, regarding the points B, D, as fixed, and C movable along the line QC, we must inquire what must be the position of C upon that line, (or what relation FC and BF must bear to each other,) that the time through BC, with the uniform velocity v, plus the time through CD, with the uniform velocity v', shall be a minimum. Now, this is evidently an ordinary question of maxima and minima; it is, in fact, identical with Fermat's problem concerning refraction above mentioned, and the solution is precisely similar; BCD will be described in a minimum of time, when the two lines BC, CD, make angles with the vertical, whose sines are to each other as the velocities v and v' with which they are described. This gives at once

\[
\frac{v'}{v} = \sin \text{ICD} \quad \text{or} \quad \frac{v'}{v} = \sin \text{ICB} \quad \text{or} \quad \sin \text{ICD} = \sin \text{ICB} \]

that is, (since sin HCB = d'y/d's', and sin ICD = d'y/d's')

\[
\frac{v'd'y}{d'y} - \frac{vd's'}{d'y} = 0; \quad \ldots \ldots (a)
\]

or, since \( \frac{v'd'y}{d'y} \) is the consecutive value of \( \frac{vd's'}{d'y} \),

\[
\frac{d'y}{d'y} = 0; \quad \ldots \ldots (b)
\]

whence we get

\[
\frac{vd's'}{d'y} = \text{constant} = a.
\]

This is the relation required between the differentials, or the differential equation of the curve, for v is given in functions of x. On the supposition of uniform gravity, we have \( v = \sqrt{g} \), and writing \( \sqrt{g} \) for a to make both sides homogenous,

\[
\frac{d's'}{d'y} = \sqrt{g} \quad \text{or} \quad x \left(1 + \frac{dx^2}{dy^2}\right) = a,
\]

the equation of a cycloid, whose base is the horizontal line AK. Such is the solution of James Bernoulli, cleared of the geometrical form which embarrasses and obscure, and expressed, as he probably would have expressed it, in the present state of symbolic reasoning.

There is one peculiarity, however, in the question of ordinary maxima and minima, to which the problem is here reduced, viz., that the quantity to be made a maximum or minimum is itself a differential expression, or infinitely small magnitude. This does not at all affect the truth of the conclusion, which is independent of the absolute magnitude of the lines and velocities concerned, but it does the manner of treating it. In problems of maxima and minima, the quantities concerned are supposed to vary by increments infinitely smaller than the quantities themselves. Now, the variation of the length of FC, or the differential of FC (d'y), on the supposition that C changes its place on QC, cannot be expressed by d dy, because it would thus be confound-
ISOPERIMETRICAL PROBLEMS.

Isoperimetrical Problems.

ed with the variation it undergoes, when (by the shifting of the ordinate QC to its consecutive position RD) QC attains its consecutive value $1D = dy + d d y$.

There are two ways in which this difficulty may be avoided. The first is the one we have above taken, viz. resolting the question of the maximum or minimum, as a separate and independent problem, and then adapting the conclusion so obtained to the particular case in question; accordingly this is the course pursued at first by the Bernoullis; but, not to mention the want of analytical neatness in such a mode of proceeding, the questions of maxima and minima, which thus arise, would in most cases be found of extreme difficulty, and their subsequent adaptation to infinitely small quantities a matter of uncommon deficiency. The other method consists in looking on the difficulty (in its true light) as merely one of notation, and obviating it by a refinement in that point, viz., by employing a new characteristic $\delta$ for that hypothesis of differentiation, by which the point C shifts, as it were, from one curve, BCD, to another infinitely near it, along the fixed ordinate, and a new name variation for this peculiar change in the value of $dy$. We have here the origin of the calculus of variations; and the manner in which this simple artifice enables us to combine the question of the minimum, with the peculiar circumstances of the case where it arises, cannot be better shewn than by the very instance before us.

It is, first of all, evident, that as $\delta$ means nothing more than differentiation, on another hypothesis, all the rules of the differential calculus must be attended to in the management of the new symbol, only making the variations of such quantities as do not change on this hypothesis, zero. Thus,

$$\delta dx = 0, \delta y = 0, \delta y' = 0,$$

because the length of BF is given, and the velocities through BF and CD are uniform. Again,

$$\delta (dy + dy') = 0, or \delta dy' = -\delta dy,$$

because GD = $dy + dy'$ is invariable. So,

$$3\left(\frac{ds}{v} + \frac{ds}{v'}\right) = 0, or \delta \frac{ds}{v} + \delta \frac{ds}{v'} = 0; \ldots \ldots (a)$$

by the condition of the minimum. Now,

$$\delta ds = 3\sqrt{dx^2 + dy^2} = \frac{dy}{\sqrt{dx^2 + dy^2}} = \delta y,$$

and,

$$3 ds = \frac{dy}{\sqrt{dx^2 + dy^2}} = \frac{dy}{ds} \delta dy.$$

So that our equation (a) becomes

$$\frac{dy}{ds} \delta y - \frac{dy}{ds} \delta y = 0;$$

and here, as in all problems of maxima and minima, the variation $\delta d y$ divides off, and leaves

$$\frac{dy}{vds} - \frac{dy}{vds} = 0;$$

the same equation as before.

By the aid of this principle of James Bernoulli, we are already in a condition to resolve a variety of problems. In the present instance, it is easy to see in what manner it supplies the place of the metaphysical principle of his brother's solution; but, without at present stopping to examine the farther cases to which it is applicable, we will continue to trace the history of the subject; and it fortunately happens (which can hardly be said of any other branch of mathematical science,) that in this the order of invention is precisely the one calculated to afford the most distinct and luminous view of it to one unacquainted with the subject, and to give him a radical knowledge of its principles.

James Bernoulli, having resolved his brother's problem, proposed, in his turn, the celebrated defiance, which at once centered the attention of the mathematical world upon these researches, and which has imposed the name of isoperimetrical problems on all which depend on similar principles. In the Leipzig Acts, 1697, appeared, accompanied with the promise of a pecuniary reward to his brother, in case of a complete solution, a programma requiring the nature of a curve, in which a certain integral expression ($\int y^2 dx$ or $\int x^2 dy$ being the ordinate, and s the arc) shall be greater or less than in any other curve of the same length between its extreme extremities.

We have here the first instance of a question of what is called relative maxima and minima, that is, where the curve in which a certain integral (A) is to be made a maximum or minimum, is to be selected, not from among all curves whatever, but only from such as have at least one property in common expressed by some other integral (B), which, in the present instance, is

$$\int ds = \int dx \sqrt{1 + \left(\frac{dy}{x}\right)^2}.$$
of the three properties, viz. (A) that of the maximum, and (B) and (C), the two common properties, affords an equation of the above form between the three variations $C e, D d, E e$; from which, eliminating any two of them, the coefficient of the other, put equal to zero, gives the differential equation of the curve.

This is, in fact, the identical process by which an ordinary question of maxima and minima would be treated, in the case where a certain function $P$ of two (or any number) of variables $u$ and $v$ is to be made a maximum, the variables being related to each other by a given equation $Q = 0$. The differentiation of the latter assigns one relation between their variations, viz.

$$\frac{d Q}{d u} \frac{\partial}{\partial u} + \frac{d Q}{d v} \frac{\partial}{\partial v} \psi = 0,$$

while the condition of the maximum gives \( d P = 0 \), or

$$\frac{d P}{d u} \frac{\partial}{\partial u} + \frac{d P}{d v} \frac{\partial}{\partial v} \psi = 0,$$

from which eliminating one of the arbitrary variations, the resulting equation will have the other for a divisor, and the remaining factor put equal to zero, gives that equation which holds good between the variables only in the case of the maximum or minimum. These variables, in the present case, are the consecutive ordinates $y', y''$, &c. of the curve sought, and thus we see the reason why the final equation so obtained is a differential equation of the curve.

Such was the state, however rudely expressed in the symbolic language and mixed geometry of those days, in which the problem was left by James Bernoulli, (in his Analysis magni problematis Isoperimetrici, Leip- sic actis, 1701); and although his brother, in a Memoir published by the French Academy in 1718, exhibited it in a more compact and elegant form, and thence took occasion, most unfairly, to arrogate to himself a large share of its merit, such was nearly the state in which it was found by Euler in 1738. It is true, that John Bernoulli, in this Memoir, had remarked a certain symmetry in the terms of his fundamental equations, which, pursued, would have led him to anticipate one of Euler's most elegant and general conclusions, but he appears (as well as some subsequent writers who have given an account of his labours,) to have confounded this with a thing of the same kind which obtains in his final, or specific equations, as he calls them, in virtue of which they are complete differentials, (of which we have an instance in the equation (c) of our first solution of the brachystochrone,) and which is not universal, or of any very extensive use in the theory of these problems. Our countryman Brook Taylor, too, in his Methodus Incrementorum (1715), considered the subject, and though he added little to the stock of knowledge, and nothing to that of facility or distinctness, yet he there first employed a general mode of representing the maximum property, viz. by $f(V dx)$, where he takes $d V = M d x + N d y + L d z$, and thus may be considered as having afforded the first handle to a general and systematic analysis.

The progress of invention had hitherto been tardy, and that of generalization next to nothing, when the subject was resumed by Euler, in a series of Memoirs in the Petrolitical Commentaries, and in a work expressly on the subject, entitled Methodus inventioni linearum curvam maximis minimis proprietate gaudentes, (1744). To whatever part of the mathematics this wonderful man turned his attention, obscurity seems to have fled his presence. It is impossible to exhibit a more luminous view of the principles of the subject.
than he has taken in this latter work. In his Memoirs, (Acad. Petropol. tom. vi. vii. and viii.) the novelty of the course he was pursuing, as well as the superfluous difficulties which usually hang on the origin of invention, had betrayed him into some errors, arising chiefly from too extensive an application of the principle of James Bernoulli, which makes the maximum property common to the curve and its elementary portions; but these he speedily rectified: and a sketch of his method, while it will put the solution of all ordinary isoperimetrical problems in the reader's power, will serve as the best practical introduction to the calculus of variations, which (however closely connected with the subject in an historical point of view) we cannot help regarding as a great deal too abstract to be made the basis of an explanation of its principles without some preparation of the kind.

Isoperimetrical problems, then, are distributed by Euler into classes, according to the number of properties they involve, or of ordinates, which must be made to vary in their analysis. The first class consists of absolute maxima and minima, where one integral $\int V \, dx$ is to be made a maximum or minimum, between limits any how determined. The rest, where, besides this condition, others are superadded, viz. that certain other integrals $\int W \, d\alpha, \int Z \, d\alpha, \&c.$ are to be given, are called, in general, questions of relative maxima or minima. To begin with the former, to which, as we shall soon see, all the rest are reducible.

Prop.

If $\int V \, dx$ be an absolute maximum or minimum for the whole curve, it will be so for every infinitely small part of it, provided $V$ be some determinate function of $x, y, p = \frac{dy}{dx}, q = \frac{d^2y}{dx^2}, r = \frac{d^3y}{dx^3}, \&c.$ involving no integral expressions.

Whatever be the order ($n$) of the highest differential co-efficient contained in $V$, imagine twice that number of ordinates erected at equal distances ($dx$) from $y$, and from each other, so as to form a series of ordinates $y_1, y_2, y_3, \ldots \ldots y_n, \ldots \ldots y_{2n}$, of which let the middle one $y_n$ vary by the quantity $n^2 = 2y_n$ (Fig. 4.), all those on each side of it remain ing invariable, so as to make one element $m \cdot n \cdot o$ of the Isoperimetrical Problems.

and we may suppose

$$dV = M \cdot dx + N \cdot dy + P \cdot dp + Q \cdot dq.$$ 

If we now conceive the integral $\int V \, dx$ resolved into its elements, thus,

$$\int V \, dx = \&c., \int W \, d\alpha + \int V \, dx + \int V_i \, dx + \int V_2 \, dx + \int V_3 \, dx + \&c.$$

we must first inquire which of these elements are affected by the variation of the element $m \cdot n \cdot o$ of the curve. Now, we have,

1st, $\int V \, dx = o,$ $\int W \, d\alpha = o, \int V_i \, dx = o,$ $\int V_2 \, dx = o,$ $\int V_3 \, dx = o,$ $\&c.$

so that the only values of $p_i$, which are affected by the variation of $y_n$ (being those which contain $y_n$), are $p_i$ and $p_2$; and these give

$$\int p_i = \frac{\partial y_n}{\partial y} = \frac{\partial y}{\partial x}, \int p_2 = \frac{\partial y}{\partial x}.$$ 

In like manner, the only values of $q \left(= \frac{d^2y}{dx^2}\right)$ which vary, are those whose expressions in terms of three consecutive ordinates, contain the variable one $y_n$, that is,

$$q = \frac{y_n - 2y_{n-1} + y_{n-2}}{dx^2}, q_1 = \frac{y_n - 2y_{n-2} + y_{n-3}}{dx^2}, q_1 = \frac{y_n - 2y_{n-2} + y_{n-3}}{dx^2}, q_1 = \frac{y_n - 2y_{n-2} + y_{n-3}}{dx^2},$$

which give

$$\int q = \frac{y_n}{dx^2}, \int q_1 = -2 \frac{\partial y_n}{\partial x^2}, \int q_1 = \frac{\partial y_n}{dx^2}.$$ 

and, in the same way, the variations of the higher differential co-efficients might be found, the numerical co-efficients being those of a binomial $1 - 1$ raised to the successive powers $1, 2, 3, \&c.$

Hence $V, V, V_1, \ldots \ldots V_n$ (or $V_0$), being the only values of $V$ which contain these quantities, are the only ones affected by the variation of the ordinate $y_n$, so that the only portion of the integral $\int V \, dx$, which varies by the variation of $m \cdot n \cdot o$ is that consisting of the elements $V \, dx + V_1 \, dx + V_2 \, dx$.

Fig. 4.

Representing then the whole integral by

$$A + \left\{ V \, dx + V_1 \, dx + V_2 \, dx \right\} + B,$$

$A$ and $B$ are invariable, and the condition of the maximum cannot therefore be satisfied unless the nature of the curve be such as to render this elementary portion a maximum.

A train of reasoning precisely similar, only longer in its details, is applicable to the higher values of $n$. When, however, $V$ involves an integral, as, for instance, the arc $z = \int dx \sqrt{1 + p^2}$, since every succeeding value of this is affected by a variation in any part of its extent, it will thus affect every succeeding value of $V$; and the rest of the integral represented above by $B$, not being invariable, the principle of James Bernoulli ceases to be true in this case. Still less can it be extended to cases where $V$ involves a quantity not given, but implicitly, by an unintegrable differential equation, as in the problem to find the curve of swiftest descent in a resisting medium, to which Euler himself erroneously ap-
ISOPERIMETRICAL PROBLEMS.

325

Prop.

The same supposition respecting \( V \) being made, to determine the relation between \( y \) and \( x \), which renders \( \int V \, dx \) a maximum or minimum.

We have here to make the element of the integral a maximum; or, which comes to the same thing, the variation of the whole integral due to that of one ordinate equal to zero; that is, (in the case we have been considering),

\[
\begin{align*}
\int V \, dx + V_x \, dx + V_y \, dy + \int V \, dx &= 0; \\
\frac{dV}{dx} + \frac{dV}{dy} &= 0.
\end{align*}
\]

Now, we have

\[
\frac{dV}{dx} = M + N \frac{dy}{dx} + P \frac{dp}{dx} + Q \frac{dq}{dx},
\]

wherever the variations of \( x, y, p, q \), (being infinitely small.) Substituting, first, for \( x, y, \frac{dp}{dx}, \frac{dq}{dx}, \) and their consecutive values, the expressions before found, we get

\[
\begin{align*}
\frac{dV}{dx} &= + Q \frac{dy}{dx} + P \frac{dp}{dx}; \\
\frac{dV}{dy} &= -P \frac{dy}{dx} + Q \frac{dq}{dx};
\end{align*}
\]

and the sum of these put equal to zero gives

\[
\begin{align*}
N &= \frac{P}{dx} \frac{dy}{dx} + \frac{Q}{dx} \frac{dq}{dx}, \\
P &= \frac{dy}{dx} + \frac{Q}{dx} \frac{dq}{dx}.
\end{align*}
\]

In this equation, we may now write \( N \) and \( P \) for \( N_x \) and \( P_x \), from which we differ only by infinitesimals, when we obtain

\[
0 = N \frac{1}{dx} \frac{dP}{dx} + \frac{1}{dx^2} d^2 P.
\]

Had we considered differential co-efficients of a higher order, by varying \( y_1 \) or \( y_2 \), &c. or at once analysed the general case, the process would have been precisely similar, and we should have arrived at the equation

\[
0 = N \frac{1}{dx} dP + \frac{1}{dx^2} d^2 P + \frac{1}{dx^3} d^3 P + &c.; (A)
\]

which is the general formula of Euler. It enables us
to resolve any problem of absolute maxima, however complicated, where \( V \) involves no integral sign. As an example of the manner of its application, we will take the solid of least resistance of Newton.

The resistance being represented by

\[
\int \frac{y \, dy}{dx} \, dx + \int \frac{y \, dy}{1 + \frac{p^2}{dx}} \, dx,
\]

here, then,

\[
V = \left( \frac{y \, dy}{dx} \right) \, dx + \left( \frac{y \, dy}{1 + \frac{p^2}{dx}} \right) \, dx,
\]

and the succeeding value of \( V \) being unaffected by the variation of the element \( \frac{dx}{B} \), \( B \) is now invariable, so that here Bernoulli's principle holds good, even when \( V \) is a function of \( x \) as in the second case of his own programma.

Prop.

Required the nature of a curve which shall give \( \int N \, dx \) a greater or less value than any other curve in which that of \( \int W \, dx \) is the same.

Here two ordinates must be made to vary; but their variations being independent, and infinitely small, the variations they cause in the two integrals may be computed separately, and their sum taken for the joint effect. Now, let \( x \) and \( y \) be the variations of the two consecutive ordinates (\( x, y \), and \( x + \delta x, y + \delta y \)), and let \( P \) or \( P' \) be the variation produced in \( \int V \, dx \) by the variation of \( y \), then, by reason of the uniformity which must subsist between all operations which relate to the consecutive points of the same curve, \( P, \delta y \), or \( P', \delta y \), will be the variation produced in it by the variation of the consecutive ordinate, and therefore \( P \) or \( P', \delta y \), or \( P', \delta y \), will be the whole variation of \( \int V \, dx \) owing to the simultaneous change of both ordinates. In like manner, if \( Q \), be the variation of \( \int W \, dx \), caused by that of \( y \), \( Q \) or \( Q ' \), or \( Q' \), will be the joint effect of those of \( y \) and \( y \). The condition of maximum then gives

\[
P + P' = 0, \quad \text{or} \quad P + (P + P') d = 0.
\]

And the invariability of \( \int W \, dx \) affords another equa-
ISOPERIMETRICAL PROBLEMS.

The problem of isoperimetrical maxima and minima is thus reduced at once, and in all its generality to that of absolute extrema for the preceding demonstration applies to all cases. We need only add to any one of the properties the others, multiplied each by an arbitrary constant, and then make the sum an absolute maximum or minimum. As a single instance, let us inquire what curve, under a given circumstance, contains the greatest area, or in which \( \int f d x \) being given, \( \int y d x \) shall be a maximum. Here the quantity to be made an absolute maximum is \( (y + a \sqrt{1 + p^2}) dx \); and \( V \) in this case being a function of \( y \) and \( p \) only, the equation (B) holds good, and gives

\[
y + a \sqrt{1 + p^2} = \frac{ap}{\sqrt{1 + p^2}} + c
\]

which reduced, affords

\[
p \left( \frac{dy}{dx} \right) = \sqrt{a^2 - (y - c)^2} \quad y - c
\]

and integrating,

\[(x - b)^2 + (y - c)^2 = a^2\]

the general equation of a circle.

In the work above cited, Euler extended his researches successfully and correctly to the case where the quantity \( V \), under the integral sign, involves one or more indeterminate integrals, or expressions given by an unintegrable differential equation, as well as where the function to be made a maximum is not merely a single integral, but a function of one or more combined; as, for example, where \( \int f d x \) is to be a maximum, \( \int d s \) being given; but of these the necessary limits of this article preclude anything beyond this historical notice. It now only remained to discover some general method of treating isoperimetrical problems, which should dispense with the resolution of integrals into their elementary portions, and reduce their treatment to a regular series of purely analytical processes. This desideratum was supplied by Lagrange (in two memoirs, published in the Mélanges de Turin, tomes ii. and iv. 1760, 1770) by one of his first and greatest discoveries, the calculus of variations, and with such complete success, that nothing beyond it can be expected in future. Euler, with a memorable candour, of which, perhaps, no parallel instance can be produced in the annals of science, and which forms a striking contrast with the passages we have had occasion to notice in the early history of the subject, was the first to acknowledge its superiority over his own methods; and, disdaining those feelings of jealous rivalry the circumstances of the case were so peculiarly calculated to excite, hastened to become the commentator of the new method, and to substitute it in the place of his own. The principle of the calculus of variations, and its connection with the present subject, has been purposely kept in view in the preceding pages, and will have been already been made sufficiently evident. For the detail of its processes, and an account of its successive improvements, as well as for the demonstration of the theorem we shall require, the reader is referred to the article Calculus of Variations.

The essential distinction between this mode of treating isoperimetrical problems and Euler's is this, that the latter estimates the change produced in an integral \( \int f d x \) by the variation of one, or, at most, a limited number of ordinates; whereas the former considers the change effected in it by the continuous variation of the ordinate along the whole extent of the curve, infinitely small indeed in quantity, but regulated by a perfectly arbitrary law. The variation of \( \int f d x \) is determined, which it undergoes, not by the change of one element only of the curve, but by the whole curve ABCD (Fig. 5.) Fig. 5.
This treatise, but that of 1807, is entitled System of Temperament, or the equal temperament of the musical scale, consists of 12 equal semitones, of the value $1 + \sqrt{2} = 51 \Sigma + f + \frac{4}{3}g$ m.

This system derives its chief consequence from the great number of writers, and the respectability of several of those who have appeared as its advocates; among those who have fallen under our notice, we remember the names of D’Alembert, Broadwood, Cevillo, Cladni, Courperin, Crotch, Davis, Des Cartes, Emerson, Euler, Kirnberger, Kellmann, Marpurg, Merzick, Mersennus, Rameau, Riccio, Scrogs, Sorge, Sulzer, Vogler, &c.

It is plain from the account given by most of the writers alluded to, that they had neither submitted this system to the test of experiment, or thoroughly calculated and considered the harmonic effects of its grossly tempered chords, the thirds and the sixths especially; while many of them were utterly unacquainted with the true nature and limits of the musical scale, as appears from their statements, and as to what could or could not be done, owing to the immutable relations which any one of the tempered chords has with several others, and of the whole combined, in a regular doulent.

In page 273 of our ninth volume, we have inserted a Table of the full particulars of a system, very carefully and minutely calculated, which Mr. Farey discovered in 1807, and first announced in the Philosophical Magazine, vol. xxviii. p. 65, not for the purpose of recommending or advocating the isometric system, of which we are now treating, as being adapted to use; but for the purpose of shewing a practicable mode of exhibiting a new system, so indefinitely near to the true isometric, that all its merits and defects might thereby be shewn, and the controversy so long subsisting regarding this system, ended by an appeal to actual and indisputable experiment.

In pursuing the same object, Mr. Farey has very recently recommended, in the periodical work above quoted, vol. xli. p. 447, the undertaking of an experimental chromatic organ, on a scale sufficiently extended to admit of exhibiting two or more octaves, of the great scale of intervals, 612 in the octave, which is given under our article Interval, so contrived, that the
merits of the isontonic, in common with a great number of other systems which have been proposed, may be put to the test of sufficient trial in musical performance: by the use of those 12 Listonian notes, which approach nearest to the true isontonic notes respectively, or those of any other system, which may be submitted to this trial.

The Table of the true isontonic system, which we are now about to present to our readers, is exactly similar in its arrangement, and was calculated for the purpose of comparison with that of Mr. Farey's system, approximating to it, which has already been referred to in our ninth volume, p. 273, except that the 3d column there, which exclusively pertains to Mr. Farey's first system, now contains those 12 notes of his enlarged Listonian scale, which he has recently recommended to be tried in performance, as substitutes for the "strict isontonic notes, which all the following columns of the Table now given, are occupied with.

Before we arrive at the printing of Temperament, in our work, we may hope to be able to announce that the experiments above alluded to have been made, and their results, and to give all the further particulars, in a tabular form, regarding the system of 12 notes, which are now contained in our third column below.

</table>

In pages 273 and 274 of its volume, which has been quoted, the sums of the beats in each of the six latter columns of the above Table will be found, compared with similar sums of the beats of Mr. Farey's equal temperament; and several other comparisons and averages, by which the very near co-incidence of these two systems are shown: the total number of beats in the two Tables, differ only .0003 of a beat, out of more than 847 beads! (a)

### ISPAHAN, ISFAHAN, or SFAHAN, a city of Persia, in the province of Ispah, situated towards the south part of a very extensive plain, on the north bank of the river Zainderoud, which is not fordable in spring, and is crossed by several fine bridges. This city, which during centuries was the capital of the empire, and yet remains pre-eminent in population and commerce, enjoys a delightful climate, of which the Persians have always boasted. The air is so pure, that metal bearing the highest polish does not contract rust; and it is said to possess powerful antiseptic principles. Except during a few weeks of the year, the sky is serene and unclouded, the rains are never heavy, and snow seldom lies long on the ground. The seasons are so regular, that it is considered a point of indifference whether the market places be covered or open.

Isfahan, in its most prosperous days, was surrounded by a wall 20 miles in circuit; but the inhabited part of the city is now restricted to a space of between two and three miles in diameter. Every where it is surrounded by ruins, extending to a great distance. Some of its most extensive suburbs have entirely disappeared, and the most populous quarters are deserted. Beheld from the top of the highest edifices, all the buildings exhibit a light yellow colour; and, were it not for the

**Beats in 1/16 of Time**
Chardin relates, that in his time, namely between the years 1666 and 1676, there were within the walls 162 mosques, 48 colleges, 1802 caravansers, 273 baths, 12 caravanserais, and the number of houses was computed at 38,000. But the city has since undergone so many dilapidations, that, in addition to the total destruction of the walls, many of the most celebrated edifices have perished. But the Shah Maidan, or royal square, is still the finest and largest in the universe, and its bazaars and religious edifices rival any to be seen in eastern kingdoms. It is 440 paces in length, by 160 in breadth. At the distance of 25 feet from the houses it was surrounded by a canal, bordered by lofty trees, both of which are now destroyed. On the south side stands the royal mosque, a magnificent building, which was constructed by Shah Abbas in the sixteenth century. Every part of it exhibits a style of architectural ornament quite unknown in Europe. It is entered by a gate about twelve feet wide, closed by two leaves, covered with plates of solid silver, partly gilt and sculptured, which were added by Shah Sefi the First. An iron chain hangs across the outside towards the square. Within these, are fountains flowing into jasper basons, spacious courts, and extensive porticos, of which that in the centre is surmounted by a vast dome and gilt crescent, visible at the distance of four leagues on the road from Casan. All this edifice is constructed of massive stone, covered with highly varnished bricks and tiles, upon which are inscribed sentences of the Koran. Though the royal mosque has lofty minarets, they are not used for calling the people to prayers, from their overlooking the neighbouring houses, which excites the jealousy of the inhabitants. On another side of the Maidan there is a Mahometan college, called the Medrese Shah Sultan Hosein. Its entrance is gained by a lofty portico, enriched with twisted pillars of beautiful Tabriz marble, which leads through two brazen gates, the extremities of which are of silver, and their whole surface highly sculptured, and embossed with flowers and verses from the Koran. They open into a court, on the right side of which is a mosque, with a great cupola covered with lacquered tiles, and adorned externally with ornaments of pure gold. It is faced by two minarets; but they can no longer be ascended, as the stairs are destroyed, and the dome itself is falling to decay, but its interior is richly spread with variegated tiles, bearing a profusion of inscriptions. The other sides of the square are occupied, one by a high and beautiful portico, and the remaining two by small square cells with carpets, as rooms for the students, twelve in each front disposed in two stories. Here there are thirty professors, who not only instruct the youth in reading and writing, but in the languages, belles lettres, geometry, astronomy, and astrology. M. Olivier was informed, that in 1790 there were 300 or 400 pupils; but formerly, as many thousands had attended it.

The city contains few hospitals, nor are they well endowed. One stands beside an extensive caravanserai, built by Shah Abbas the Great, who erected both at the same time, that the revenue of the latter might support the proper officers of the hospital.

The palaces of the kings are enclosed in a fort of lofty walls, which are about three miles in circuit, and to which there is nothing at all comparable in Europe, whether in appearance or extent, or in the number and beauty of the edifices, dispersed over spacious gardens. In general, the front room or hall is very open, and supported by pillars exquisitely carved and gilded; while the large glass windows, through which it receives a mellow light, are curiously stained with a variety of colours. Each has a fountain in front. The palace Chehel Sitoon, or forty pillars, stands in the middle of an immense square, intersected by various canals, and planted with trees. Towards the garden, there is an open saloon supported by eighteen pillars, all inlaid with mirrors, and appearing from a distance to consist entirely of glass. The base of each pillar is marble, sculptured into the figures of four lions, so disposed that the shaft rests on the whole. Mirrors are likewise profusely arranged over the walls; and the ceiling is decorated with flowers in gilding. An arch'd recess, embellished in the same manner with glass, and portraits, leads into a spacious and splendid hall. The roof is formed in a variety of domes and figures, and is tastefully painted and gilded. Part of the walls consists of white marble, and part is covered with mirrors: they are besides ornamented with six large paintings, chiefly of Shah Ismael, and Shah Abbas the Great, in battles and in royal fêtes, which are all of considerable age, yet the colours are perfectly fresh, and the gilding surprisingly brilliant. No furniture remains here except carpets. Those of the time of Abbas, two centuries old, are superior to the fabric of the present day. Adjoining to this palace is the harem, which was erected by the second minister a few years ago, and presented to the king. The apartments are alike elegant as those of the other: the walls painted with birds, ravenous animals, and bouquets of flowers; besides which, they are resplendent with mirrors and gilttings. Here are seen the portraits of several sovereigns, particularly of the present king, for whom an establishment, complete in all its parts, is always kept in readiness, though he resides at Teheran, many miles distant. The windows of this palace display some beautiful specimens of stained glass and enamelling, disposed in couples, in honour of the monarch, together with quotations from the Koran. It appears from Chardin, that the kings of Persia have always had a number of palaces, arising from confiscations. But he observes, that of 157 which belonged to him in Isphahan, the greater part were uninhabited, and many falling to ruin.

Most of the caravansers and bazaars are very fine. Some of the former are large, and appropriated for travellers from their respective provinces; so that no difficulty occurs in finding a stranger. Short and expressive sentences are frequently inscribed on the outside, such as, "Two companions are indispensables for a traveller, a long purse and a good sword," or, "Ask for nothing more than others have previously had," and the like.

The bazaars are highly celebrated, consisting of large wide streets, arched and lighted from above. Several are covered with domes, and painted, especially in the interior, with the portraits of the heroes of the country, with combats, the figures of beasts, and similar subjects. The most extensive bazaar was formerly 600 geometrical paces in length, very broad and lofty, but we do not know that any are now so large. By means of successive communications, a passenger could traverse the whole city sheltered from the elements. A new one has been built, and those of older date repaired, by the patriotic minister Haji Mahomet Hussein Khan.

The suburb of Julfa stands on the south side of the.
A grand causeway or avenue, called the Char-baghi, or four gardens, extending 3000 paces in length by 70 in breadth, leads to the principal bridge across the river. The gardens surrounding Isphahan, and their fruits, are highly celebrated for variety and excellence. They are copiously watered by numerous channels, and contain fine fountains and pavilions; though many of both have been destroyed. The garden of Azar Gerib has always been appropriated to the culture of the fruits most esteemed in Persia. It extends a mile in length, and being formed on a declivity, is disposed in twelve terraces, supported by walls, each divided into a great number of squares, which are planted with fruit-trees, all of the same species, arranged in quincunxes. The whole district environing Isphahan and its gardens, is one of the richest in Persia; every species of grain, and all edible herbs grow luxuriantly, cotton, tobacco, saffron, madder, and saffron, are abundant. Many of the villages, however, which enlivened the scene, and contributed to the wealth of former ages, have now disappeared.

The eastern authors are not agreed regarding the origin and antiquity of Isphahan. It is affirmed by some, that its earliest name was Jangi or Cherestan; others think that it was founded by Alexander the Great. Arta.xereses captured the city in the course of the third century, after which its history is obscured during several ages. It surrendered to the great warrior Tamerlane in the year 1386, immediately on his appearing before the walls; but in consequence of an insurrection, almost its whole inhabitants were devoured to destruction.

"I conquered the city of Isphahan," says that sovereign, in his Institutes, "and trusting in the people, I delivered the castle into their hands, and the darogah whom I placed over them, they slew, with 3000 of the soldiers: and I also commanded that a general slaughter should be made of the people of Isphahan." An account was taken of 70,000 heads that were piled up in pyramids, as a testimony of the cruel victor's resentment. When the Afghans, a race from the countries to the north-east of Persia, invaded the empire, an army of 20,000 men took the suburbs of Julfa, and invested Isphahan. Mahmoud their commander, having made an unsuccessful assault on the city, commenced a strict blockade. All supplies were interrupted, and a terrible famine ensued. The people, however, willing for a time to submit to privations, became impatient under their distresses; and surrounding the bazaar, wherein the sovereign had secured himself, demanded, but in vain, to be led against the enemy. It is recorded, that horses and mules soon rose to so high a price, that none excepting the king and the wealthiest citizens could afford to purchase them for subsistence: and the animals, hitherto deemed unclean by the principles of the Mahometan religion, became welcome food. As these were exhausted, leather and the bark of trees were substituted, and at length the famished inhabitants had recourse to human flesh; many of them killed each other, many were seen cutting pieces from the dead bodies of those who had just expired; parents killed their children; and some, to terminate their calamities, became their own executioners.

The streets, the squares, and the royal gardens, were covered with carcasses; and the river Zinderoud was so corrupted, that its waters were hardly fit for use. At length the king, to avert further evils, resolved to abdicate the throne, and advancing to the camp of Mahmoud, laid the ensigns of royalty at his feet. When the Afghans took possession of the city, a large por-
Istria.

The surface of Istria is extremely unequal; part of it towards the sea is low and marshy, part, especially to the north-west, consists of precipitous mountains, from which the projection of enormous pointed rocks seems to threaten destruction to the beholder. Their sides are penetrated by caverns and grottos, incrusted within by stalactites of fantastic shapes, and numerous torrents pour down the deep ravines. The mountains are either capped with snows, bare and barren, or covered by beautiful forests, from which the marine of Venice is chiefly supplied. Hence a great diversity of climate ensues; and when one part of Istria is concealed with cold, the heat of the level ground is almost insupportable, and, as we shall afterwards illustrate, is attended with a fatal insulularity.

The valleys are of extraordinary fertility. They afford two crops annually of the ordinary kinds of grain, which is of excellent quality, and some of it exported to Hamburg. Harvests are obtained almost without the operations of agriculture. Oil and wine are abundant, and the price of the latter, which possesses remarkable strength and flavour, is so moderate as to render it attainable by every class of the people. Profitable fisheries of the tunny and anchovy are carried on in the Adriatic, where the fisherman scarcely needs to leave the shore for procuring a plentiful supply.

The inhabitants of civilized countries present fewer prominent characters than those emerging from a savage condition. Probably the natives of Istria are a mixed race, and it appears to us that the Morlachians, who are copiously disseminated in the neighbouring regions, form part of the number. Nevertheless a considerable difference is to be observed in their morals and pursuits, according to the places where they dwell. In the district of Trieste, their physical constitution bears more resemblance to that of the inhabitants of Carniola, to which they are annexed by some geographers. They are alike indifferent to the piercing cold of the mountains and the evergreen heat of the valleys, and, with their breasts bare, and feet naked, they brave the ice, and the asperity of the rocks. They are robust and active. In Venetian Istria, on the other hand, they are slothful and indolent. The fertility of the soil, and the stores of the sea, summon forth so little exertion, that in many places they are sunk in a state of apathy. Abusing the facility of procuring liquors by drinking to excess, many are afflicted by gout at an early period of life. Numerous lame persons are seen among them, which some have ascribed to the immoderate use of intoxicating draughts, and some to an original vicious personal conformation. It is probable, however, that much of the inactivity of the Istrians may be owing to the nature of their country and its climate. The presence of forests, wooded and marshy grounds, are alike pernicious to health; and it has been remarked, both in Europe and elsewhere, that, on their eradication, a sensible amelioration follows. It is affirmed that the climate is not equally fatal to native Istrians as to strangers, for many aged persons are seen here. It has also been maintained, that if their strength were developed by labour; if agriculture were in greater repute, and procured more healthful nutriment for them; if they abstained from strong liquors, and if a watchful police promoted cleanliness, which is of such vital importance, their endemic maledictions would gradually disappear.

Istria contains several towns of considerable import. Towns; of which, according to some geographers, the principal is Trieste. But as others incline to detach Trieste from this country, and annex it, along with its territory, to another, we shall briefly remark, that it is situated at the bottom of a gulf of the same name, occupying the place of the ancient Tergeste, a Roman station; that it is a city of great trade and numerous population, which chiefly began to flourish under the celebrated Empress Maria Theresa, somewhat after the middle of the preceding century. See TRIESTE. Capo d'Istria, one of the largest in the Venetian part, is usual. Capo d'Istria, is, as the capital, See Capo and Istria. The town of Pola, now an inconsiderable place, is, as re Pola—
marked by the learned Dr. Pococke, "in relation to its antiquities, to be regarded among the greatest." It stands towards the south-west extremity of Istria, but the approach to it from the sea is dangerous on account of rocks and shoals. It has a fine road, spacious and convenient, forming a basin which is completely sheltered from every wind. Pola is surrounded by walls, and defended by a citadel, a poor edifice of four bastions, wherein the Venetians kept a garrison of 15 or 20 men, and a governor, who was always a nobleman, and whose monthly allowances cost more than the whole annual pay of the military. All maritime visitors undergo the strictest examination, to guard against infection of the plague from the Levant. Nevertheless, it sometimes breaks out and makes considerable ravages. The occurrence of this calamity is attributed to the negligence of a police not sufficiently vigilant in preventing the surreptitious introduction of contraband goods, the fruits of piracy and robbery, by profligate persons dwelling on some of the neighbouring islands. The inhabitants of Pola do not exceed 600 or 700 dispersed within the walls. Here are the remains of one of the noblest amphitheatres now extant. Its exterior walls are almost entire, consisting of very large hewn stones, bound together with cramps of iron. They rise in three stories, each penetrated by 72 arcades, or 216 in whole, and are capable of containing several thousand persons. This amphitheatre, like others, is of an elliptical form, the largest diameter extending 400 feet; and in the interior is a wide subterraneous channel, supposed to have been for the purpose of carrying off water. Pola possesses other interesting antiquities; as the ruins of a temple, dedicated to Rome and Augustus, an emperor who long resisted that tribune of adulatior. Its architecture exhibits the most delicate proportions of the Corinthian order; and an inscription, testifying its original object, is still legible between the architrave and the cornice over the portico. The inhabitants of the city, however, believe that the temple was built for the worship of Pallas: and popular names are, besides, given to different antiquities, which tend to involve their foundation and uses in much perplexity. Such are the ruins called the Palace of Julia, and the Tower of Orlando. A beautiful monumental arch, simply a memorial of conjugal affection by a surviving widow, appears here in good preservation. Pola is supposed to have become a Roman colony in the time of Augustus; it was destroyed first by Attila, and afterwards by the Venetians. One of the more flourishing towns of Istria, is the seaport Rovigno, occupying a peninsula on the west coast, which is handsome and well built. The materials of the various edifices are taken from neighbouring quarries, the same that supply what are required for the structures of Venetia. The cathedral is a spacious and elegant edifice of Gothic architecture, occupying the highest part of the city, with a lofty tower. Rovigno contains about 10,000 inhabitants. The ancient Parentium, now Parenzo, was famous for a temple dedicated to Neptune, the foundations and basement of which are still visible. Otho, emperor of Germany, is said to have taken its materials for building the cathedral, which contains many curious pieces of Mosaic. A small town, called Pirano, stands in a picturesque situation, on a peninsula between the Gulf of Lagona and that of Trieste, and which is conjectured to belong to the age of Attila. In the church is an ancient vase, converted to a font, which is sculptured with a cupidian or dolphin. There are several other towns in Istria besides what are now mentioned. Most of those on the sea-coast are unhealthy, and, long ago, that of Citta Nova was represented as almost quite desolate from so disastrous a cause.

The principal exports of this country are marble, timber, fish, salt, oil, and wine.

Formerly, the population of Istria was computed at 100,000 souls; but this seems to have been only the Venetian part, and it is not unlikely that the inhabitants of the whole at present exceed double that number.

The history of Istria, which can be obtained only from meagre materials, ascends to a very early date. It is considered to have been one of the Illyrian provinces, but its ancient dimensions are not clearly ascertained. The Colchians, on returning from their celebrated expedition, are supposed to have established themselves here; and when the country was conquered by the Romans, they found the worship of Isis established in it. Istria, when united to the empire, shared in its diversified fortunes; but its history is so much interwoven with that of the neighbouring regions, that the same observation may be applied to both. We learn that Crispus, the son of the Emperor Constantine, having been banished to Pola on an accusation of an incestuous passion for his step-mother Fausta, was compelled to swallow poison. The inhabitants, believing him innocent, decreed magnificent obsequies to his memory, and Fausta soon became the victim of her own disolute conduct. The monuments yet seen in Istria testify the advanced state of the arts; but the decline of the empire admitted new and more barbarous invaders. This country at length fell under the dominion of the Venetians, and more recently it has had some participation in the troubles which agitated Europe towards the close of the preceding century.
